Lecture 2&3: nerve action potential &properties of nerve fibers

Objectives

- By the end of this lecture, the student should be able to:
- Appreciate Changes that occur through the nerve after stimulation by threshold (effective) stimulus
- Define and draw giving membrane potential in mv and time course in msec and label all components such as threshold level(firing level), depolarization, spike overshoot, repolarization and positive after potential
- -Identify different types of voltage –gated channels
- -Correlate the conductance changes with opening (activation) or closing (inactivation) of relevant gates.
- Distinguish between a local potential and an action potential.
- -Define absolute and relative refractory period on basis of excitability changes
- Classify neurons by using letters or numbers on basis of diameters and velocity.
- Define myelin sheath, myelinated and unmyelinated nerve fibers
- Describe differences in the propagation of action potential in myelinated and unmyelinated nerve fibers.
- Define all and none law.
- Differentiate monophasic, biphasic and compound action potential.

Types of Nerve Fibers

Classification According to Myelination

1- myelinated: have myelin sheath (diameter more than 1um)

1-type A fibers

-(as somatic (motor) nerves to skeletal

2-type **B** fibers

-(as preganglionic autonomic nerves).

2- unmyelinated have no myelin sheath (diameter less than 1um)

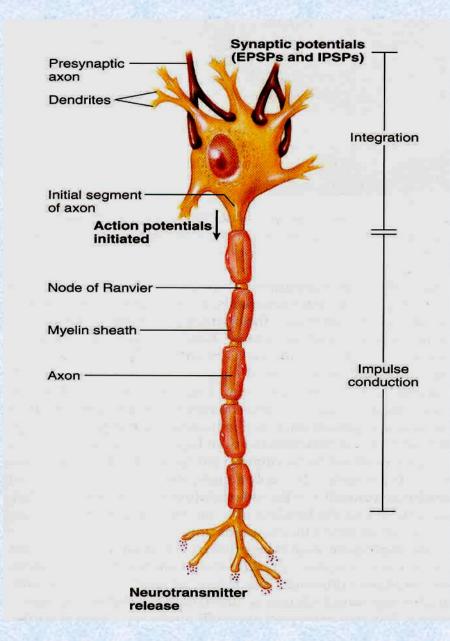

-type C postganglionic autonomic &pain fibers)

Classification According to Diameter

A, B & C fibers

Diameter: A>B>C

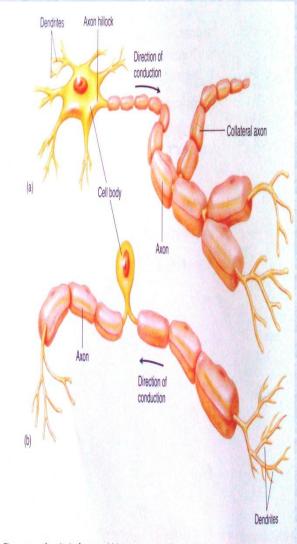

Because conduction velocity depends upon diameter, A are fastest and C are slowest

- <u>Myelin sheath</u> is formed by schwann cell which deposit lipid substance called sphingomyelin around the nerve fiber
- Interrupted at nodes of Ranvier (2-3 micron) at the junction between 2 cells.

Functions of myelin sheath

- 1-insulator/ makes ion flow across the membrane much more harder & decrease ion flow through the membrane (decreases ion leakage)
- **3- increase conduction velocity** (because ionic currents need to "jump" (from one node of Ranvier to the next)
- 4-protection
- 5- conserve energy during transmission of AP

The structure of two kinds of neurons. (a) A motor neuron and (b) a sensory neuron are depicted here.

Changes that occur in the nerve after stimulation by an effective stimulus are:-

- 1-Electrical changes
- 2- Excitability changes
- 3-Thermal changes
- 4-Chemical changes

• 1- Electrical changes

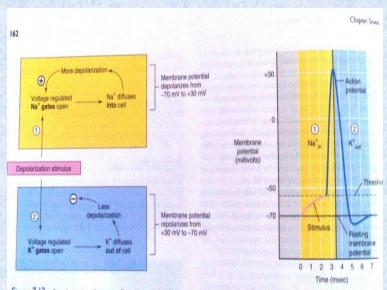

Figure 7.13 Depolarization of an axon affects Na* and K* diffusion in sequence. (1) Na* gates open and Na* diffuses into the cell. (2) After a brief

The nerve action potential

-The nerve action potential

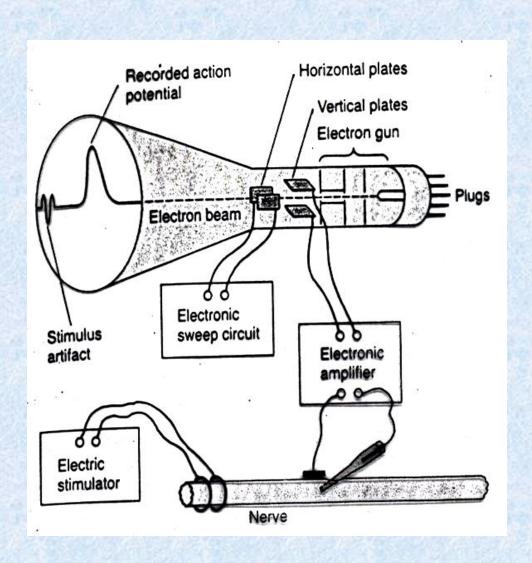

It is potential difference along nerve membrane <u>after</u>
<u>stimulation by Threshold = effective) stimulus</u>

-Nerve signals (impulses) are transmitted as nerve action potentials conducted along the nerve fiber as a wave of depolarization to its end.

-The channels necessary for nerve action potential are:-

Voltage gated Na+ & k+ channels

During action potential we use oscilloscope to measure rapid changes in membrane potential

Summary of stages of acion potential are:-

- 1-RMP:-At the <u>resting state(no stimulation)</u> the membrane is <u>polarized</u> (-ve inside = -90 mv)
- 2-Depolarization: sudden Na inflow (influx)

 → polarizesd state is lost & potential rises to positive values (reach zero & overshoot to + ve values).
- 3-Repolarization: Na channels close & K channels open & K outflow (outflux) to outside → restoration of the normal –ve RMP.

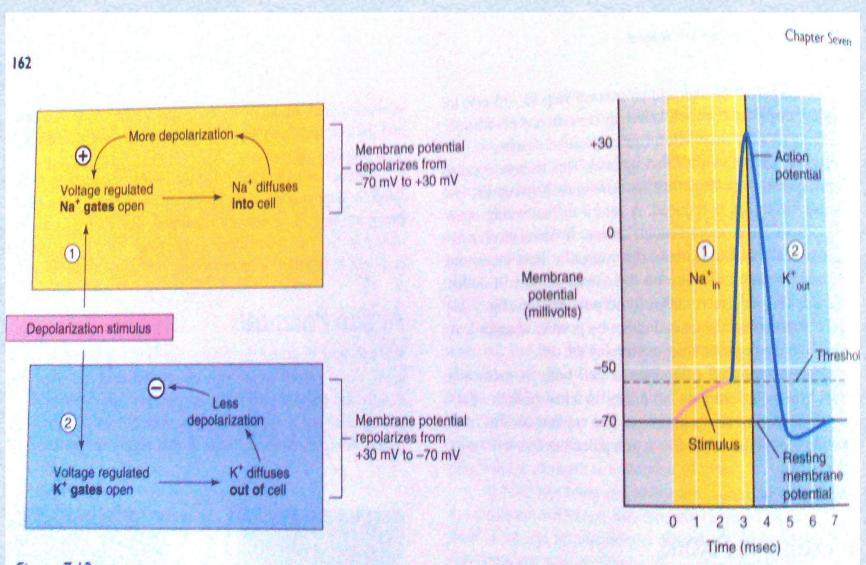

Figure 7.13 Depolarization of an axon affects Na+ and K+ diffusion in sequence. (1) Na+ gates open and Na+ diffuses into the cell. (2) After a bnef

Summary of events that causes AP (spike potential):-

1-Initiation of Action Potential (AP)& +ve feedback vicious circle that opens Na channels CAUSING DEPOLARIZATION STAGE

a- Gradual depolarization stage:-

- Threshold stimulus (An effective stimulus strong enough)->>> >to cause voltage gated Na channels to open & Na influx to inside nerve membrane >>>>> rises resting potential from-90 towards zero
- Rise of membrane potential >>>>> open more Na channels & more Na influx (+ve feedback vicious circle) until all voltage gated Na channels open.
- The increase in membrane potential from -90 to -65 mv cause explosive opening of all Na channels & Na conductance is 5000 times great → massive Na+ influx
 - so -65mv is called firing level.

b-Depolarization stage:-

- Sharp & rapid depolarization occurs & membrane potential reach zero value & then overshoot to reach + 35 mv (reversal of polarity) occurs & the inside of the cell becomes +ve
 - The peak of AP is reached at (+35 to +40 mV).
- At this value all Na + channels become refractory (begin to <u>close</u> suddenly & no more Na+ entry)
- & Depolarization ends

c-Repolarization (return to polarized state):-

Cause:- due to high K conductance(flow) to outside of nerve membrane by openning of all K channels >>>>> (K outflux carrying positivity to outside & raising negativity inside)

(Also zero flow of Na to inside as all Na channels close)

<u>causes negativity</u> inside

 Membrane returns to resting potential (drop from +35mv towards zero then to negative resting potential -90 mv)

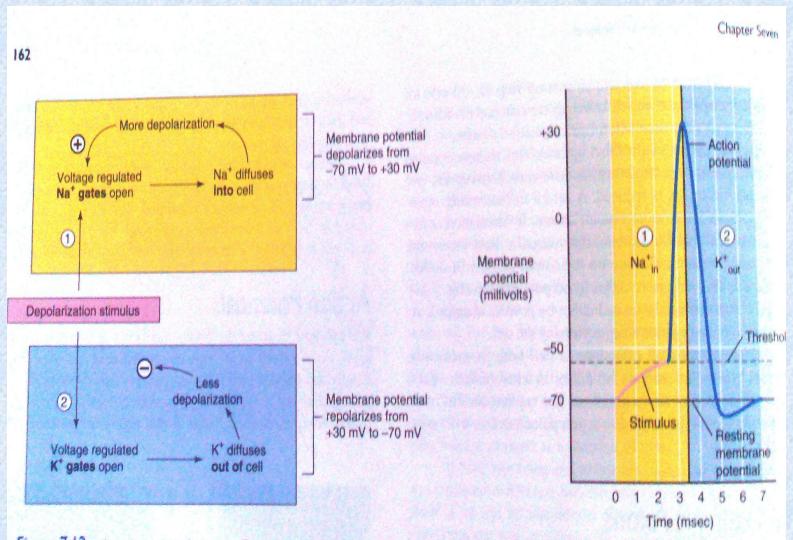

Figure 7.13 Depolarization of an axon affects Na⁺ and K⁺ diffusion in sequence. (1) Na⁺ gates open and Na⁺ diffuses into the cell. (2) After a brief

- D- <u>Positive after potential</u> (In some nerves) membrane potential becomes more negative than resting level
- (because many K channels remain open & K outflux continue- causing more -ve inside = hyperpolarized state)
- (positive after potential is wrong terminology it is historical one)

1425 - 2004

- E- Re-establishment of Na & K ionic gradients & return to resting membrane potential:-
- a- Na that had influxed in & K that had oufluxed out returned to original state by Na-K pump (active process - need ATP & ATPase)
- b- Closure of some K channels so keep some K+ inside(raise positivity inside)

-Gain of these two processses is:-

K remain inside causing some positivity to raise potential towards -90 mv

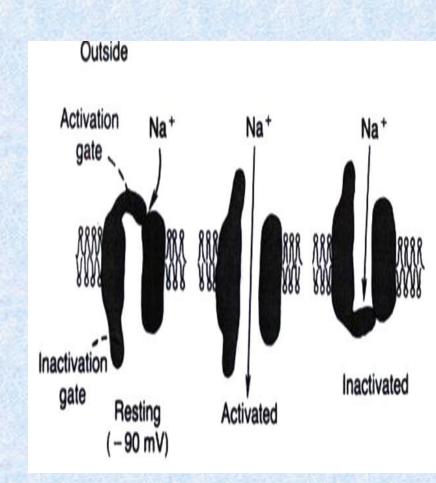

Duration of nerve action potential is 1-1.5 ms

The factors necessary for depolarization & repolarization are:-

- 1-Na voltage –gated channels important for both depolarization & repolarization
- 2- K voltage –gated channels important for repolarization

A- Voltage –gated Na channels:-

- Outer activation gates & inner inactivation gates.
- 1-Resting state:-at RMP -90 mv activation gates close & inactivation gates open ——
- No Na entry.
- 2- Activated state:-after stimulation, the membrane potential rises at a voltage between -90 to -65mv, conformational change occur & activation gates open (now both gates are open) & Na influx causing depolarization
- 3- Inactivation state: inactivation gates close slowly while the activation gate is still open & they close completely at + 35 mv & stops Na influx & repolarization begins.

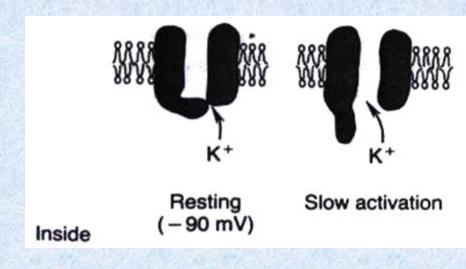

B-Voltage –gated K channels:-

1- Only one gate,

a-at RMP (resting state) the gate of K is closed & no K pass to out.

- b- after stimulation & between
 -90 to zero mv, the potassium channel opens slowly & K
 outflux begins slowly
- They open completely only when Na gates close & when Na influx stop) causing rapid repolarization

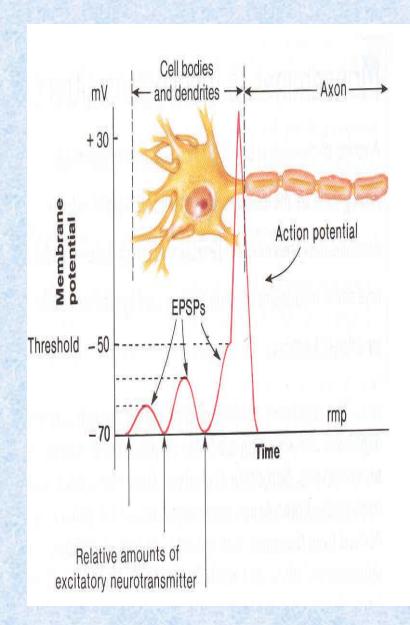

-Acute local potential (acute local response):

A very weak stimulus (not threshold) can cause local change in membrane potential e.g from -90 to -85 mv which is not sufficient for generation of AP, this is acute subthreshold potential (which is graded مشرع and does not propagate). It should increase to threshold level to produce AP.

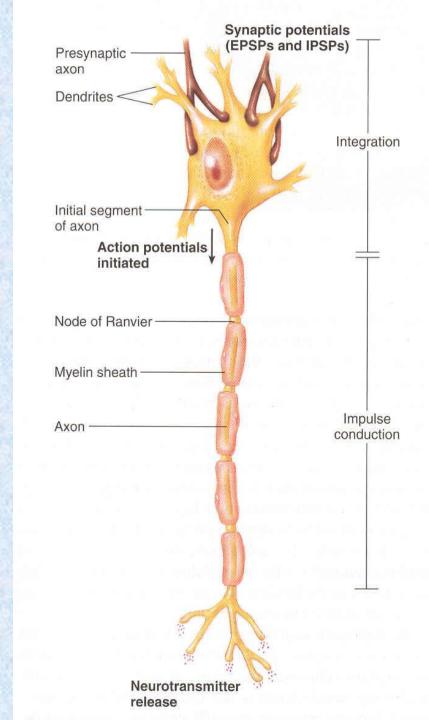

-The AP differs from local response in that AP is:-

- (1) not graded
- (2) obeys All-or None Law
- (2) propagated (conducted for long distances.

All or nothing principle:-

- The nerve respond to a threshold stimulus maximally or does not respond at all (there are no half solutions)
- Once threshold stimulus applied, it gives AP spread all over the nerve fiber
- its intensity (peak amplitude) can not increase by increasing stimulus intensity (or by suprathreshold)
- subthreshold stimulus can not elicit action potential (but produce a local response which does not obey this law)

Direction of propagation of AP:-

- In one direction from axon hillok to nerve terminal
- (experimentally) if nerve stimulated at its midportion, AP pass in both directions

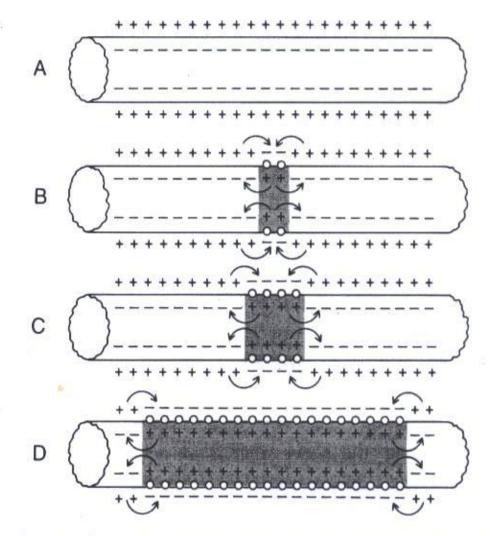

Figure 5-8 Propagation of action potentials in both directions along a conductive fiber.

Na & K conductance (flow) during action potential:-

1-At resting state, before AP:-

K conductance through K leak channels is 50-100 times as Na.

2- At onset of action potential:-

Voltage gated Na channels activated & Na conductance is 5000 folds, at the same time voltage gated K channels begin to open slowly

- 3- During depolarization :- Na conductance / K conductance > 1000 fold
- 4- At peak of AP :- Na channels close & voltage gated K channels open &

K conductance increase

- At repolarization: the ratio Na conductance / K conductance decreases.

4-At end of AP :-return to -ve potential , close voltage gated K channels & no K+ conductance

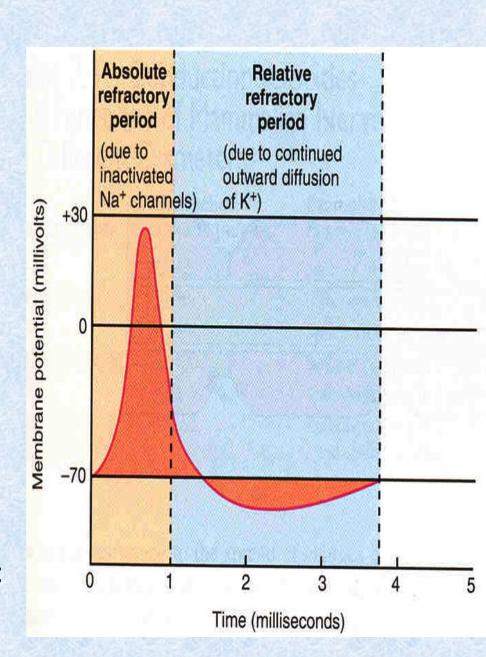

2-Excitability changes

the ability to respond to a second stimulus

1-Latent period

<u>2-absolute refractory (متمرد) period</u>

- During depolarization & early repolarization
- during it the nerve can not excited by a <u>a second stimulus</u> & a second spike action potential can not be elicited whatever strength of the stimulus (even suprathreshold)
- -(because all Na channels are already opened & Na influx occurred & a new stimulus can not open further Na channels

3- Relative refractory period:-

- -It is during the late third of repolarization (½ to 1/4 absolute refractory period in its duration)
- -it is the period during which a second action potential of low amplitude can be elicited by stimulus stronger than normal suprathreshold)

Why suprathreshol stimulus?

because:

- 1- Na channels still inactive so need stronger stim to open
- 2- rapid flow of K to outside during repolarization oppose any stimulation to occur (so need stronger stim to cause a new AP.)

<u>Propagation of action potential (Transmission of depolarization process along a nerve = spread of nerve impulse</u>

1- in myelinated nerve fibers by:-

Saltatory conduction (jumping)

√-AP occurs at nods of Ranvier & directed from node to node, through axoplasm inside & ECF outside by jumping

APs can develop only at the Nodes of Ranvier → Where

- (1) ions can relatively easily flow in & out
- (2) there are voltage-gated channels

Value:-

- 1-↑ velocity of conduction (100 m/sec in large myelinated nerve fibers in comparison to 0.25 m/sec in small unmyelinated nerve fibers)
- 2-Conserve energy for axon because only nodes depolarize (need little energy for reestablishment of Na&K ions).
- 3-Insulation by myelin sheath allow repolarization to occur rapidly (with many K channls have not open)

2- Non- myelinated nerves by :-

local circuits=Continuous Conduction =point to point

- -depolarization pass by local circuits.
- -depolarization in an area, + ve charge carried inward by Na ions flow for several 1-3 mm in the axon core & increases the voltage inside the nerve to threshold value to cause depolarization in a new area & Na channals open & depolarization spread to new areas

Recording of AP:-by cathode ray oscilloscope

1-Monophasic AP:-one microelectrode outside & one inserted into nerve fiber
2-Biphasic AP:-2 microelectodes placed on outside of nerve fibers(biphasic means one in one direction then second in second direction
