# Lecture 3 **NEURON & THE NERVE RESTING MEMBRANE POTENTIAL** الجهد الغشائي

### Lecture 1: NEURON & NERVE RESTING MEMBRANE POTENTIAL

**Objectives:-**

- By the end of this lecture, the student should be able to:
- -Identify and describe structural components of neurons and functions. •Identify Excitable tissues
- •Identify and describe different potentials & types of membrane ionic channels & equal or unequal distribution of ions across the membrane
- Identify cell membrane creating concentration and electrical gradients.
  Identify and describe diffusional and equilibrium potential
- •. Apply Nernst equation to calculate equilibrium potential.
- -Identify resting membrane potential (RMP)
- -describe genesis of resting membrane potential (RMP) and appreciate the effect of changes in ionic composition and/or permeability on genesis of RMP and the role of ions channels, and Na<sup>+</sup> K<sup>+</sup> pump
- Apply Nerst equation in calculating resting membrane potential
- -<u>Identify</u> voltmeter to measure very small membrane potential difference between inside & outside as resting membrane potential.

## Q: What are Excitable tissues إسريع الانفعال

## A: They are nerve and muscle

<u>Q: what property do excitable tissues have that makes</u> them different from other body tissues ?

A: Their membrane acts as an electric capacitor مكثف, storing opposite charges on the opposite sides of the membrane this creates:

-Resting membrane potential(<u>RMP</u>) of high value ( -70 to -90 mV ) compared to other body cells ( in RBC , for example MP= -5 mV ) .

This high RMP makes the nerve or muscle membrane function as a capacitor , that can "discharge" يفرغ producing large voltage changes ( action potentials ).

#### Neuron:-

-<u>DIF;-</u>unit of function of the central nervous system, mostly anterior horn cell in the spinal cord supply skeletal muscle <u>Parts of motor neuron & function</u> of each part:

1- Soma (cell body)

2-Dendrites carry nerve impulses from surroundings to the soma 3 Axon hillock at which nerve impulses begin & pass in one direction from soma to the axon( nerve fiber) then to axon terminal. 4-Axon and axon terminal end on skeletal muscle

Figure 8.24 A spinal reflex. This reflex involves three types of neurons: a sensory neuron, an association neuron (interneuron), and a somatic mo neuron at the spinal cord level.

Q: What is the membrane potential (<u>MP</u>)? It is the difference in potential (voltage) between the inner side & outer side of the membrane (nerve membrane) Q: What are the states of MP?

(1) Resting Membrane Potential (RMP) : value of MP in

a "resting " state (unstimulated excitable nerve membrane). It ranges between -70 and -90 mV in different excitable tissue cells, in large myelinated nerves <u>= -90 mV</u>

<u>(2) Graded Potential (Local Response)</u>: MP in a stimulated cell (nerve) that is producing a local , <u>non-</u> <u>propagated potential</u> غير منتشر ( an electrical change which is measurable only in the immediate vicinity منطقة مجاوره of the cell but not far from it ).

(3) Action potential (AP): MP in case of a nerve that is generating a <u>propagated</u> منتشر electrical potential after stimulation by effective stimulus ( an electrical potential which can be measured even at long distances far from the cell-body of the nerve)

#### **<u>Q</u>: What are the types of membrane ionic channels ?**

(1) <u>Leak (-نسرب-Diffusion , Passive ) channels</u>:

- Pores in the cell-membrane which are open all the time, therefore ions diffuse through them <u>according to the</u> ion Concentration Gradient.
- قنوات ذات بوابات تعمل بالجهد الكهربي: <u>Voltage-gated channels</u> (2) open when the cell-membrane is <u>electrically activated</u>.

(3) <u>Chemically-gated ( ligand-gated ) channels</u> :

open by chemical neurotransmitters at neuromuscular junctions & synapses (connections b/w neurons).

#### **Basic physics of membrane potential**

- Nerve has semipermeable membrane separating the ECF from the ICF .

1- <u>K is high inside</u> the nerve membrane & <u>low outside</u>
 → therefore potassium continuously diffuses through <u>the</u>
 <u>K<sup>+</sup> leak channels</u> from inside the cell to outside .Why?

-So diffusion of k ions through membrane occurs from high conc inside to outside carrying +ve charge with it→ build up of electropositivity outside & electronegativity inside

2- <u>Na is high outside</u> membrane & <u>very low inside</u> membrane so the direction of the Na<sup>+</sup> chemical ( concentration gradient) gradient is inward  $\rightarrow$  and sodium continuously diffuses through the <u>Na<sup>+</sup> leak channels</u> from outside ( the extracellular fluid , ECF) to inside the cell ( the intracellular fluid , ICF).  $\rightarrow$  build up of electronegativity outside & electropositivity inside.

## NERNST EQUATION

#### -The Potassium Nernst ( Equilibrium ) potential

 Nerst calculate the level of concentration potential of ions across the membrane that prevent net diffusion of ions to inside or outside

#### Nernst made a hypothesis which said that if we suppose that

- (1) the ECF and ICF contained ONLY potassium ion,
- (2) and that the cell-membrane was freely permeable to K
- $\rightarrow$  then K+ will diffuse down its concentration (chemical) gradient (<u>via the K+ leak</u>
- <u>channels</u>) <u>from inside the cell to outside</u>, carrying with it +ve charges to the outside,

-This progressively increasing the negativity on the inner side of the membrane because we are losing +ve charges from inside ).

- At this goes on and on , negative charges build inside an <u>opposing negative electrical</u>
- <u>potential</u>, tending to prevent the exit of the +ve potassium ions
- (force tends to keep K inside).

This negative electrical potential will grow INSIDE until it becomes

the concentration مضادة وتبطل strong enough to balance and counteract

gradient which tends to push K+ OUTSIDE

<u>\*</u>When this electrical gradient ( electrical force ), which tends to keep K+ inside equals( = ) the concentration gradient ( which tends to push K+ outside )  $\rightarrow$  there will be no net K+ movement across the membrane .

The membrane potential (MP) in that case is called:-

<u>Nernst Potential for K+ ( or K+Equilibrium or Diffusion Potential )</u>

It equals = -94 mV (The -ve charge always refers to the inside of the cell relative to the outside )

(This value was calculated by Nernst equation)

E.M.F (mV) = + 61 log K+ conc. Inside = -94MV K+ Conc outside

#### -The SODIUM Nernst ( Equilibrium ) potential

Nernst made a hypothesis which said that if we suppose that:-

(1) the ECF and ICF contained ONLY sodium ions ,(2) and that the nerve-membrane was freely permeable to Na+

 $\rightarrow$  then Na+ will diffuse down its concentration gradient to the <u>Inside</u> of the cell, carrying with it +ve charges , and progressively decreasing the <u>negativity</u> on the inner side of the membrane

As this goes on and on , and as the positive charges build <u>inside</u>, an <u>opposing Electrical</u> <u>Potential</u> begins to develop , tending to prevent the +ve Na+ ions from entering.

<u>This electrical potential will grow until it becomes strong enough to balance and counteract</u> the <u>concentration gradient</u> which tends to push Na+ inside .

When this electrical gradient (force), which tends to drive (PUSH) Na+ outside equals = the concentration gradient (which tends to push Na+ in)  $\rightarrow$  there will be no Na+ movement across the membrane.

The MP potential in that case is called:-

<u>Nernst Potential for Na+ (</u> or Na+ Equilibrium or Diffusion Potential ) = +61 mV. (The charge always refers to the inside of the cell )

- What determines the magnitude (value) of the Equilibrium (Nernst) Potential ?
- The ratio of the ion concentration on the two sides of the membrane ( inside&outside).
- The value of this potential EMF can be determined by : <u>Nernst potential = electromotive force (EMF)</u>
- E.M.F (mV) = + 61 x log <u>lon conc. Inside</u> lon Conc outside
- -The greater the ratio( it means ion conc inside is higher than outside) the greater the force for ions to diffuse in one direction (from inside to outside)
  - -for K = 94 mv & for Na = + 61 mv
- ((it is -ve for K & + ve for Na (K diffuses out so ↓ the ratio & Na diffuses inside so ↑ the ratio))

# The resting membrane potential of nerves

# RESTING MEMBRANE POTENTIAL الجهد الكهربائي الغشائي في حالة عدم النشاط

**DIF:-** it is potential difference across nerve membrane during rest (without stimulation)

Value:- -90 mv in <u>large</u> nerve fibers ( -ve inside) (range-70 mv TO -90 mv) (the -ve or +ve sign referes to the inside of the membrane) -The membrane is <u>polarized</u>

- Two questions should be asked :
- Q1: What are the factors that make the inside of the cell negative ?
- Q2: and give the RMP of large myelinated nerves the value of 90 mvolts( or -70 to -90 mV )?

Depend mainly on transport properties of resting membrane, the factors that make the inside of the cell negative :-

- 1- Contribution of K & Na diffusion potential through <u>Na & K leak channels</u> of nerve membrane
- 2-Active transport of Na & K ions (Na/K pump)
- 3- Negative ions inside membrane as phosphate sulphate & proteins

## **Origin of RMP:**

## **<u>1- Contribution of K diffusion potential:-</u>**

- N.B/K diffusion contributes far more to membrane potential than Na diffusion.
- (1)<u>At rest</u>, K inside is 35 times higher than outside
- K+ leak channels → more K+ diffuses to outside than Na+ to inside, because <u>K leak channels</u> are far more permeable to K than Na about <u>50-100 time</u> due to small size of K molecules) → more potassium lost than sodium gained → net loss of +ve ions from inside the cell → <u>more negative inside</u>
- (net **<u>K</u>OUTFLUX TO OUTSIDE** causing –ve inside)

#### (1) Applying Nernst Equation:-

- -K inside is 35 times higher than outside (35/1)
- Nernst potential = 61mv x log 35/1(1.54) = -94 mv,
- (if K is the only ion act on membrane  $\rightarrow \underline{RMP} = -94$  mv with negativity inside the nerve) 1425-2004

• 2- Contribution of Na diffusion potential:-

**<u>Na leak channels</u>** :- have **Slight** permeability to Na ions from **outside to inside.(why slight?)** 

- Nernst potential = + 61 x log (Na inside/Na outside = 0.1) = + 61 x log 0.1 = + 61 mv

-Nernst potential for Na inside membrane =  $\pm$  61mv. (if Na is the only ion act on membrane  $\rightarrow$ RMP =  $\pm$  61mv with positivity inside the nerve Na diffusion potential = + 61mv & that of K = - 94 mv
 -using this values in Goldman equation

## (to calculate diffusion potential when membrane permeable for several ions)

**\*\*** net value of the internal membrane potential of

about <u>-86 mv</u>

N.B/ almost all of this determined by K diffusion

<u>(because membrane is 50- 100 times permeable to K than to</u> <u>Na</u>

• i.e potassium potential has the upper hand.

• 3- contribution of Na/K PUMP:-

Pumps 3Na to outside & 2 K to inside, causing
 → net loss of +ve ions ,loss of + ve charge
 from inside , create negativity about <u>- 4mv</u>
 inside

-so net membrane potential will be :-(-86 mv) + (-4mv) = -90 mv

4- Effect of Large intracellular anions(negative ions) (proteins, sulphates & phosphates) very low effect

## Measuring membrane potential

## VOLTMETER

- <u>To measure very small membrane potential difference</u> <u>between inside & outside as resting membrane</u> <u>potential . How?</u>
- -a small filled pipette containing electrolyte solution put inside the nerve fiber & another electrode is placed in the outside & <u>membrane potential</u> <u>difference between inside & outside measued</u>
