Bacterial Structure / Function & Bacterial Genetics

Prof. Hanan Habib & Dr. Albdulaziz Al~Khattaf

College of Medicine, Department of Pathology, KSU

Objectives-Bacterial Structure & Function

- Define the cellular organization of bacteria and know the differences between Eukaryotes and Prokaryotes.
- Know major structures of bacteria and its functions.
- Know the structure of cell wall of bacteria including the differences between Gram positive and Gram negative bacteria and main functions.

Objectives, cont.,

- Know the external structures of bacteria with and functions.
- Know the cytosol and internal structures of bacteria.
- Describe bacterial spores and its application in the practice of medicine.

Objectives- Bacterial Genetics

- Know basic information about bacterial genetics and replication of bacteria.
- Describe plasmids, its origin, types and its importance in clinical practice.
- Recalls genetics variations, including; mutation and mechanisms of gene transfer and its implication on bacterial resistance to antimicrobial agents.

Definition

Bacteria: Is a heterogenous group of uni-cellular organisms, about 1-8 µm in diameter

Bacteria is a Prokaryote (has a primative nucleus):

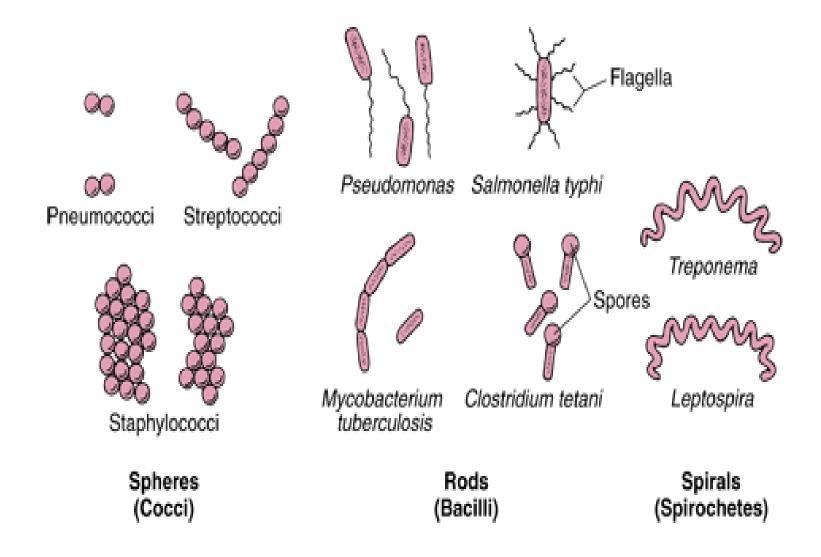

- ~ one chromosome
- no nuclear membrane
- no mitochondria
- ~ no sterols

Bacteria contain Plasmids: an extra piece of DNA.

Shapes of Bacteria

- Spherical / Oval......Cocci
- Rods.....Bacilli
- Very short Bacilli...Coccobacilli
- Tapered endFusiform
- Club~shaped / Curved....Vibrio
- Helical / Spiral....Spirochaetes

Shapes of Bacteria

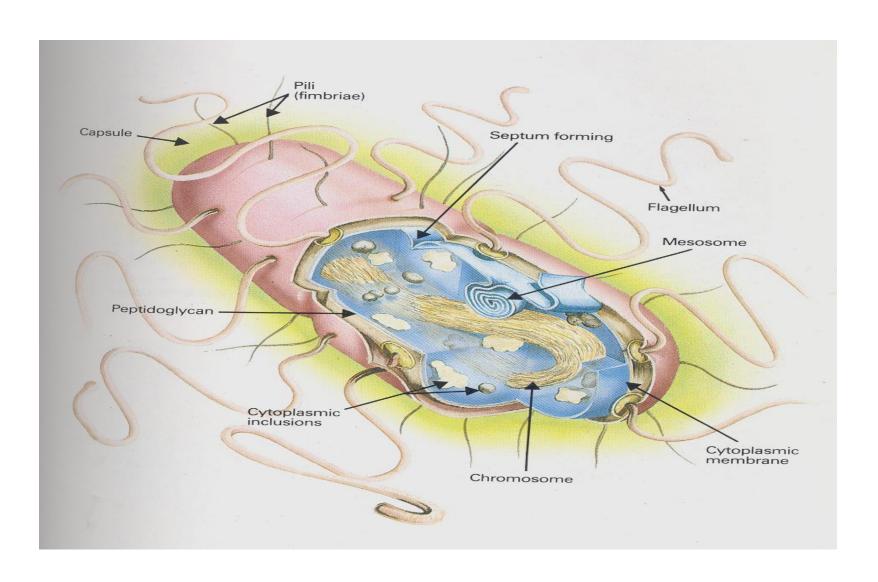

Arrangements of Bacteria

Arrangements among Cocci:

- Pairs.....Diplococci
- Chains......Streptococci
- Clusters.....Staphylococci
- In four.....Tetrad
- Palisades.....Corynebacterium

Major Structures of Bacteria

Cell Wall of Bacteria

• Bacteria are cells with rigid cell wall surround cytoplasmic membrane and internal structures.

Functions of cell wall:

- Rigidity
- Shapes bacteria
- Protection
- Porous / permeable to low molecular weight molecules
- Cell division
- Antigenic determinants

Cell Wall of Bacteria

• Two groups of bacteria depending on reaction to **GRAM STAIN**:

GRAM POSITIVE BACTERIA: stain blue/purple by Gram stain

GRAM NEGATIVE BACTERIA: stain red by Gram stain

Note: Mycoplasma is a bacteria that is naturally have no cell wall.

Chemical structure of bacterial cell wall:

• Peptidoglycan:

Rigid part, mucopeptide composed of alternating strands of *N*- acetyl muramic acid and *N*- acetyle glucosamine linked with peptide sub units.

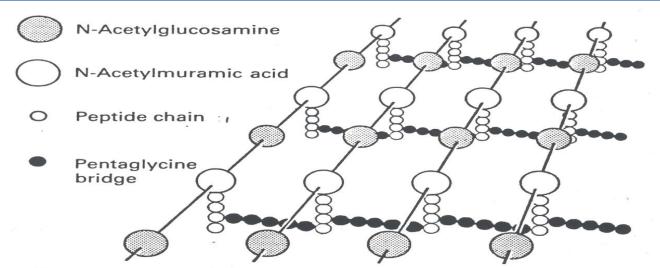

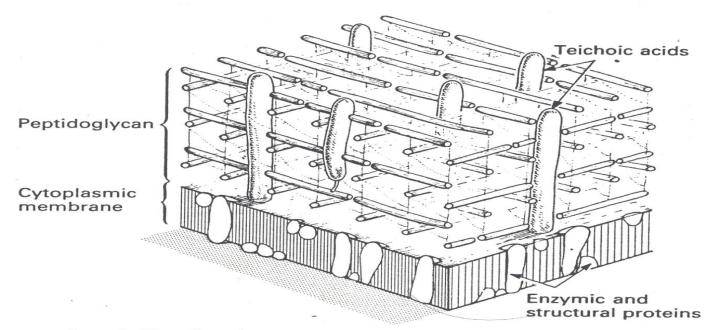

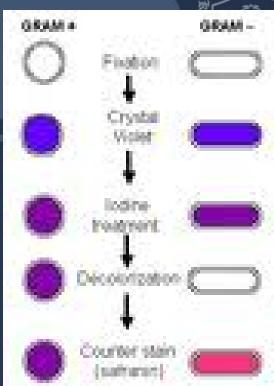

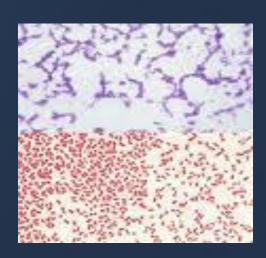

Diagram to show chemical structure of cross-linking in peptidoglycan component of cell walls. From Sharon N The Bacterial Cell Wall. Copyright (C) 1969 by Scientific American Inc. All rights reserved.

Three-dimensional representation of Gram-positive bacterial cell wall.

Cell Wall of Gram Negative Bacteria

- Thin Peptidoglycan
- Outer membrane that contains:
 - specific proteins (porins) important in the transport of hydrophilic molecules
 - lipopolysaccharide & lipid (ENDOTOXIN)

Cell Wall of Gram Positive Bacteria

- Peptidoglycan **thicker** than Gram negative bacteria.
- Closely associated with cytoplasmic membrane.
- Teichoic acid: anchors cell wall to cell membrane, epithelial cell adhesion.
- Antigens : ~ polysaccharides (Lancefield)
 - protein (Griffith)

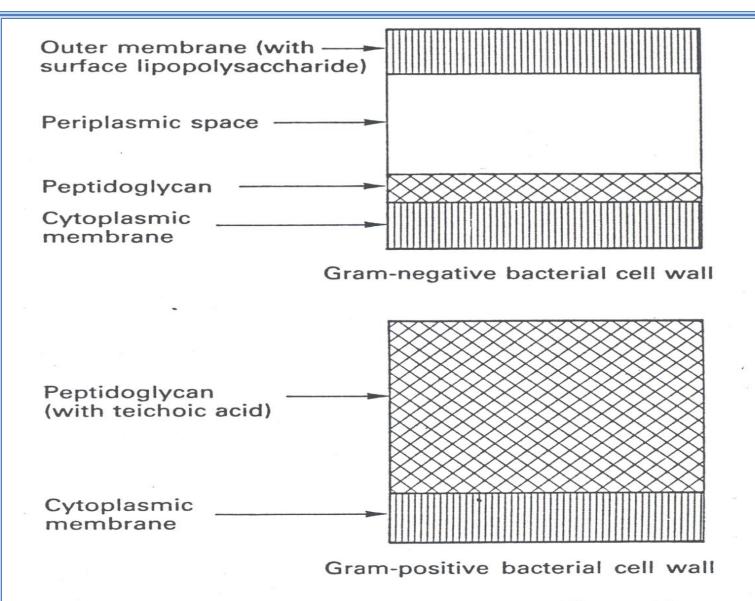

Diagram showing the structure of Gram-negative and Gram-positive bacterial cell walls.

External Structures of Bacteria

External protrude from the cell into the environment.:

- Flagella
- Pili
- Capsule

Flagella

- Composed of protein **FLAGELLIN**.
- Helical filaments
- Found in Gram positive & Gram negative bacteria.

Distribution:

- ~ Peritrichous
- ~ Monotrichous
- ~ Lophotrichous

Structure of Flagella

Basal Body: a protein arranged as rings on central rod (4 ring in Gram negative, 2 ring in Gram positive).

-outer pair of rings: only in Gram negative, pushed through outer membrane.

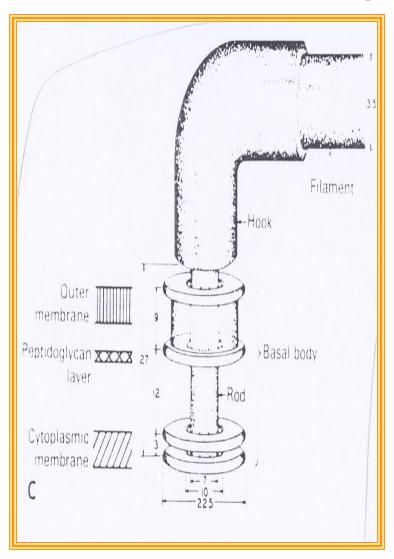

~ inner pair of rings: inserted into peptidoglycan & cytoplasmic membrane.

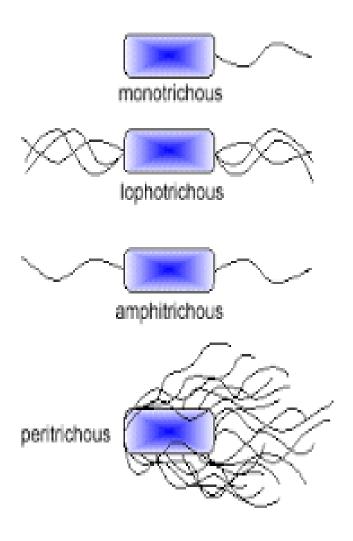

Hook: bent structure -act as joint

Long Filament: Flagellin protein

Function of Flagella: motility & chemotaxis

Structure & Distribution of Flagella

Pili

Fine short filaments extruding from cytoplasmic membrane.

Found on the surface of many Gram negative & Gram positive bacteria.

Composed of protein Pilin.

Two classes:

- 1~ Common pili (fimbriae): covers the surface—responsible for: adhesion & colonization
- 2~ Sex pili: in some bacteria only, responsible for conjugation.

Capsule

- Amorphous material surrounds bacteria.
- Usually polysaccharide
- Occasionally protein
- Function: ~ Inhibits phagocytosis
 - Acts as *Virulence factor* in some bacteria by assessing attachment to the surfaces.

Cytoplasmic Membrane

- Cytoplasmic membrane (cell membrane)
 - Double layered structure composed of phospholipid & protein
 - Act as semi~ permeable membrane (passive diffusion)
 - Site of numerous enzymes involved in active transport of nutrients and various metabolic processes

Internal Structures of Bacteria

Mesosomes: convoluted invaginations of cytoplasmic membrane.

Function:

- »Involved in DNA segregation during cell division & respiratory activity
- » Contain receptors involved in chemotaxis
- » Permeability barrier (active transport of solutes).

Core of Bacteria

• Composed of: Cytoplasmic inclusions

Nucleoid (nuclear body)

Ribosome

1. Cytoplasmic inclusions:

- Nutritional storage granules, examples:
 - ~ Volutin
 - ~ Lipid
 - ~ Starch / or Glycogen

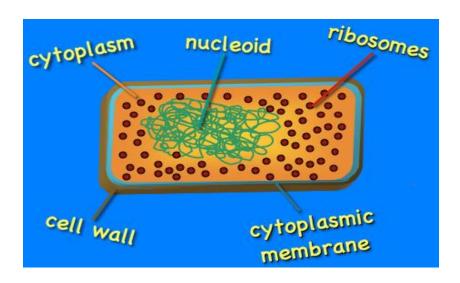

Nucleoid (Nuclear Body)

- Circular single stranded chromosome (bacteria genome or DNA)
- No nuclear membrane
- DNA undergoes semi-conservative replication, bidirectional from a fixed point

•

Ribosomes of Bacteria

- Distributed throughout the cytoplasm
- Site of protein synthesis
- Composed of RNA and protein

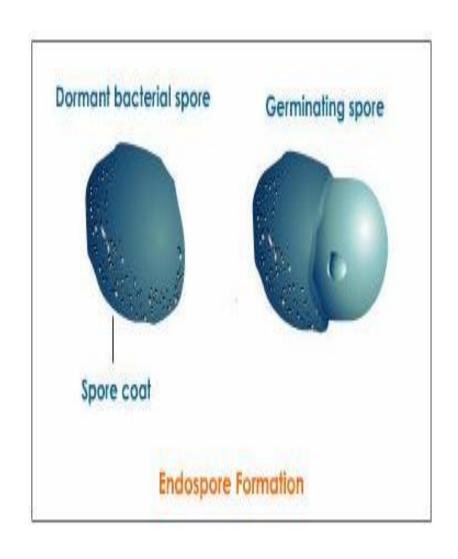

Spores of Bacteria

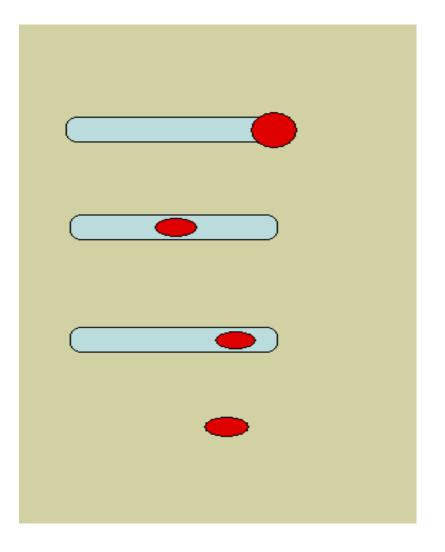

- Small ,dense, metabolically inactive , nonreproductive structures produced by *Bacillus* & Clostridium
- Enables the bacteria to survive adverse environmental conditions.
- Contain high concentration of Calcium dipicolonate.
- Resistant to heat, dissecation & disinfectants
- Often remain associated with the cell wall

Spores of Bacteria-cont.

- Spores are described as:
- 1 ~ **Terminal** spores
- 2~ Sub-terminal spores
- 3~ Central spores
- Spores germinate when growth conditions become favorable to produce vegetative cells.
- <u>Application in medical practice</u>: spore preparations used for checking the efficacy of **Autoclaves**, eg. *Bacillus subtilis & Bacillus sterothermophilus*.

Spores of Bacteria

BACTERIAL GENETICS

Bacterial Genetics- definitions

- **Genetics** is the study of inheritance and variation.
- Genetic information encoded in DNA.

Function of genetic material:

- 1 Replication of the genome
- 2~ Expression of DNA to mRNA then to protein.

Definitions-cont.

- Genotype: the complete set of genetic determinants of an organism.
- Phenotype: expression of specific genetic material.
- Wild type: reference (parent) strain~ active. Mutant: progeny with mutation.

2 types of DNA in bacteria

- ~ Chromosomal
- Extra-chromosomal (Plasmid).

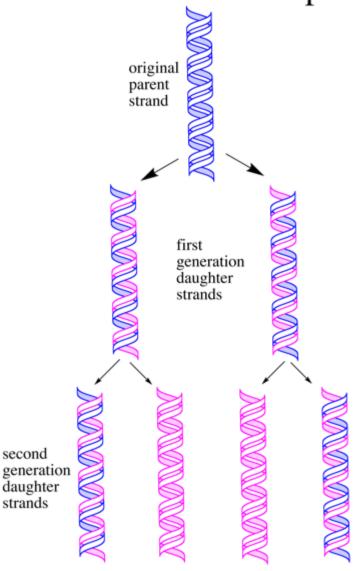

Bacterial Chromosomes

- Haploid, circular molecule of double stranded~ DNA attached to cell membrane. No nuclear membrane (prokaryotes).
- DNA a double helical structure, genetic code in Purine and Pyrimidine bases of nucleotides that makes DNA strand.
- 3 bases comprise one code, each triplet codon codes for one amino acid.
- Replication is semi-conservative.

CARYOTES AND EUCARYOTES procaryote cell wall single, circular chromosome cytoplasm cell membrane rich in (site of cellular ribosomes plasmid respiration) eucaryote mitochondrion cell (site of cellular respiration) membrane nuclear membrane nucleus lysosome cytoplasm rough endoplasmic smooth reticulum endoplasmic (ribosomes) reticulum Golgi apparatus

Cytoplasmic membrane Mesosome Chromosome of circular double-stranded DNA

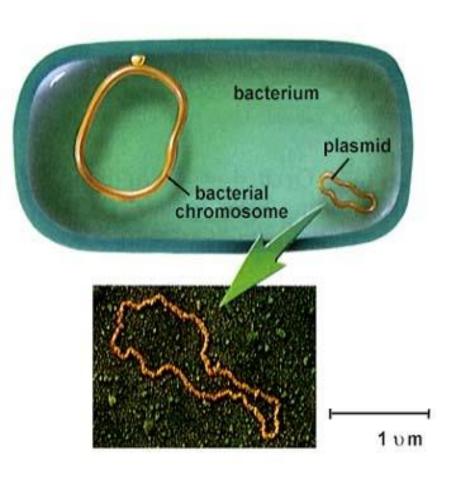

Semiconservative Replication

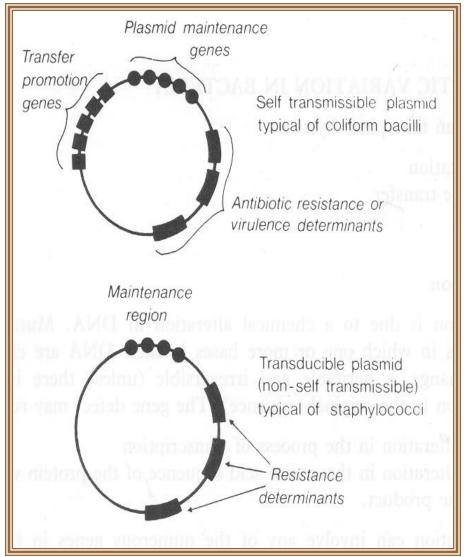

Plasmids

- Extra chromosomal DNA composed of double stranded-DNA.
- Found in most species of bacteria.
- Origin?
- Govern their own replication
- Application : Genetic exchange, amplify genes
- Transfer by conjugation
- Unrelated plasmids coexist together only

Plasmids

Types of Plasmids

- 1~ **R~plasmids**: genes code for antibiotic resistance particularly Gram negative bacteria.
- 2-Col-plasmids: in Enterobacteria, codes for extracellular toxins.
- 3~ F-plasmids: (fertility) factor, transfer of chromosome during mating.

Genetic variation in bacteria:

takes place by:

- 1 Mutations
- 2-Gene transfer

Mutation

- Inheritable changes in the structure of genes (DNA).
- Chemical changes in one or more bases of DNA.

Mutation / gene defect leads to alteration in:

- Transcription,
- Amino acid sequence,
- Function eg. Bacteria resistant to antibiotic.

Classification of Mutation

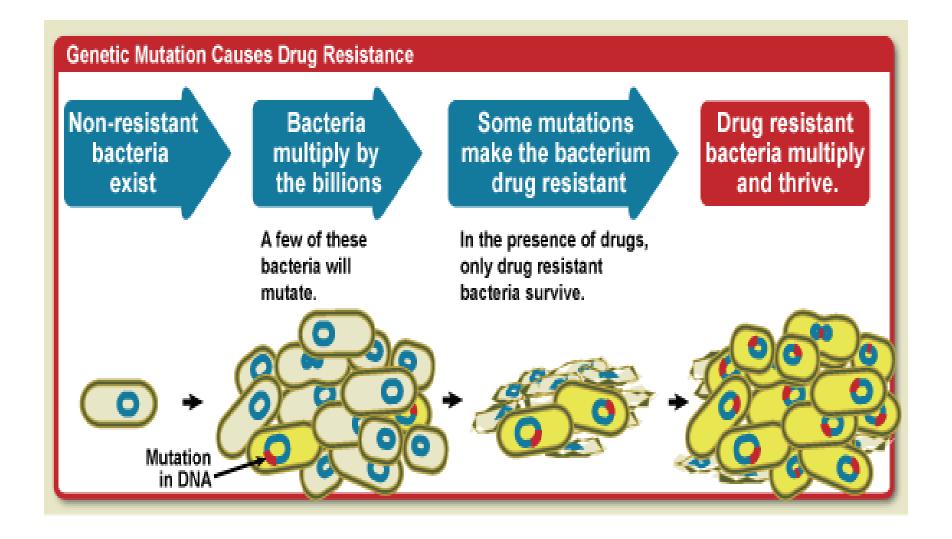

Depends on biological sequencing:

1 - Resistance mutation: affect structure of cell protein. Main application in medical practice.

Bacteria become resistant to antibiotics

- 2~ Auxotrophic mutation: affect biosynthetic enzyme resulting in a nutritional requirement of mutant cell.
- 3~ Lethal mutation.

Mutation Causes Antimicrobial Resistance

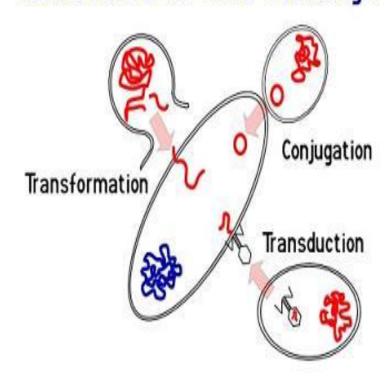

Gene Transfer Among Bacteria

Three mechanisms:

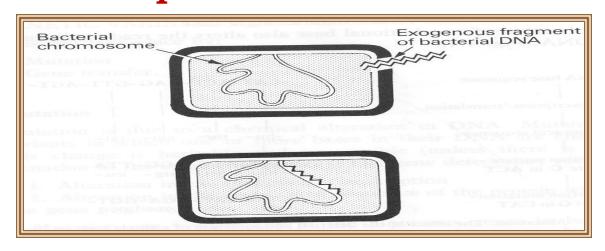

- 1~ Transformation
- 2~ Transduction
- 3~ Conjugation.

Mechanisms of Gene Exchange

Transformation

- A fragment of exogenous naked bacterial DNA are taken up and absorbed into recipient cells.
- Common in *Haemophilus influenzae & Streptococcus pneumoniae*. Bacteria become resistant to Ampicillin.

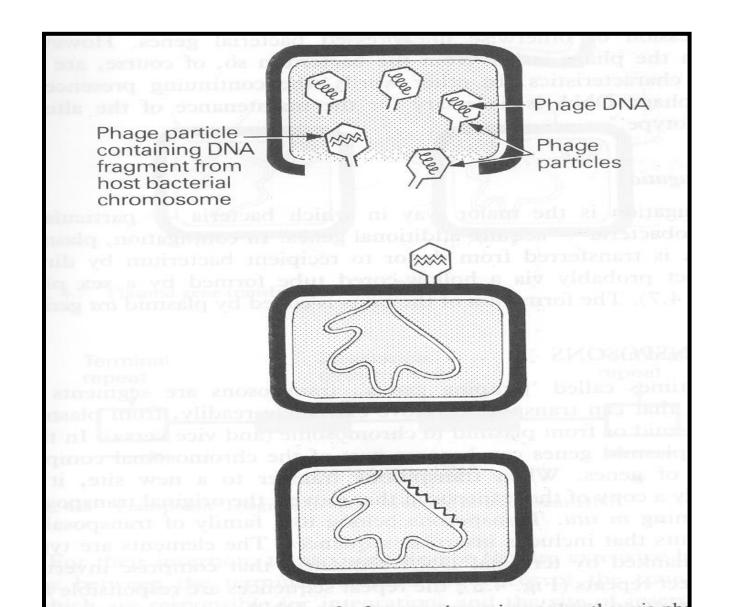

Transduction

• Phage mediated transfer of genetic information from donor to recipient cells.

Example:

- Beta Lactamase production in Staphylococcus aureus: Bacteria becomes resistant to penicillin.
- Toxin production in *Corynebacterium* diphtheriae.

Transduction

Conjugation

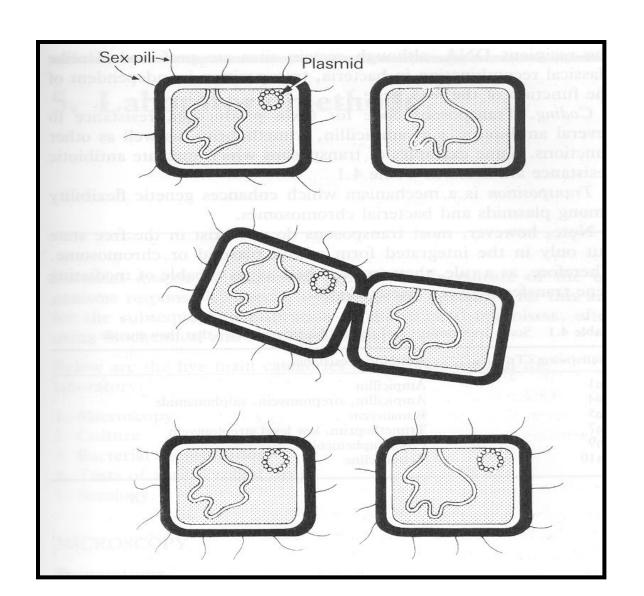

- Major way bacteria acquire additional genes.
- Plasmid mediated
- Cell contact required and genes reside on plasmid resident within donor cells transfer to recipient cell (mating).
- Conjugation is the common way of transfer of genes resistance to antibiotics among bacteria in hospitals.

Conjugation

- Mediated by plasmid called **F factor** (fertility).
- Gene encode changes in surface by producing a **sex pilus** .this facilitates capture of F^- cells and the formation of a conjugation bridge through which DNA passes from F^+ into F^- cells.

•

Conjugation in Bacteria

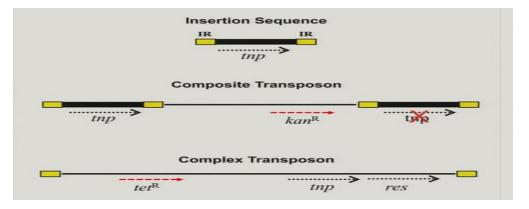

Genetic Recombination

- After gene transfer, there are three possible fates:
- 1-Exogenous DNA degraded by nuclease.
- 2-Stabilized by circulization and become plasmid.
- 3~ Form a partially hybrid chromosome with segment derived from each source.

Transposable Elements

- Genetic units capable of mediating own transfer from chromosome to another, from location to other on same chromosome or between plasmid and chromosome or phage DNA.
- Types: 1~ Transposons.
 - 2~ Insertion sequence
