

Cardiovascular system

FOURTH LECTURE

KEY

- Doctor's slides
- Notes/extra explanation
- Important
- Only on boys' slides
- Only on girls' slides

هذا العمل لا يغني عن المصدر الأساسي للمذاكرة

Objectives:

1. Identify the components of the cardiovascular system.
2. Describe the Heart in regard to (position, chambers and valves).
3. Describe the Blood vessels (Arteries, Veins and Capillaries).
4. Describe the Portal System.
5. Describe the Functional and Anatomical end arteries.
6. Describe the Arteriovenous Anastomosis.
7. Describe the component of the blood and its function.
8. Describe the Sinusoids.

The Cardiovascular System

Consist of :

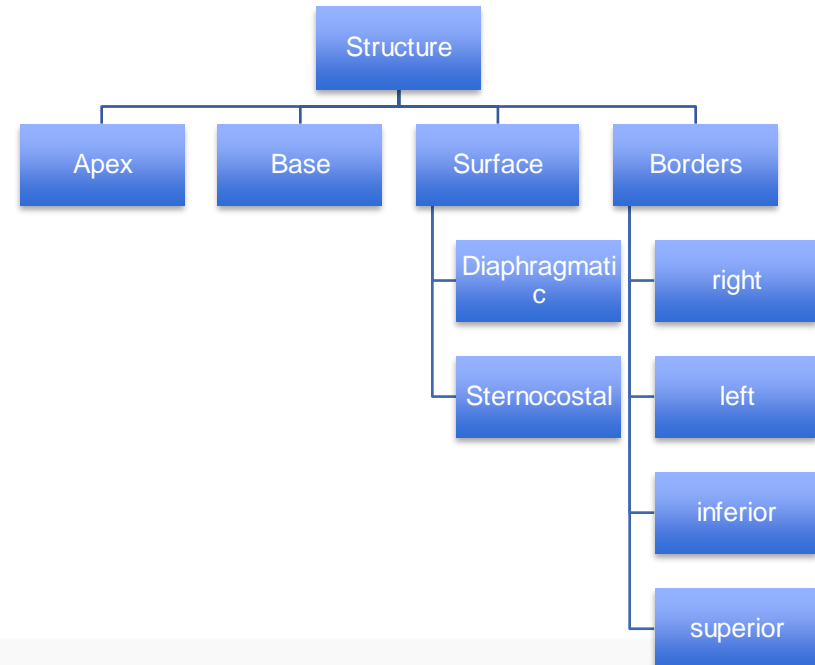

1. Heart: pumps blood throughout the body .
2. Blood vessels: a network of tubules.
3. Blood

Functions:

1. It is a transportation system which uses the blood as the transport vehicle .
2. It carries oxygen , nutrients, cell wastes, hormones and many other substances vital for body homeostasis.
3. It provides forces to move the blood around the body .

Structure of the heart:

- It is a hollow, cone shaped muscular pump that keeps circulation going on
- It is the size of the hand's fist of the same person.
- It has : Apex , base surface and borders

Location of the heart

It is located in the thoracic cavity in a place known as the **Middle Mediastinum** between the two pleural sacs.

o Enclosed by a double sac of serous membrane (**Pericardium**).

o 2/3 of the heart lies to the left of median plane.

o The outer wall of the heart is made up of three layers:

Epicardium

Myocardium
(muscle of
the heart)

Endocardium

Chambers of the heart

Atria:

- They are two (Right & Left).
- Superior in position.
- They are the receiving chambers.
- They have thin walls.
- The upper part of each atrium is the **Auricle**.
- The **Right** Atrium receives the venous blood coming to the heart.
- The **Left** Atrium receives arterial blood coming from the lungs.

VENTRICLES:

- The inferior chambers.
- They are two (right & left).
- They have thick walls.
- They are the discharging chambers (actual pumps).
- Their contraction propels blood out of the heart into the circulation.
- The left ventricle forms the apex of the heart.

Valves of the heart

The heart has FOUR VALVES:

Two Atrio-Ventricular valves.

One Aortic Semilunar valve.

One Pulmonary Semilunar valve

ATRIOVENTRICULAR VALVES:

- Location: **between atria & ventricles.**
- Function: **they allow the blood to flow in one direction from the atria to the ventricles.**
- 1-Right AVV (Tricuspid).
- 2-Left AVV (Bicuspid/Mitral).

SEMILUNAR VALVES (AORTIC & PULMONARY):

- Location: **between the right and left ventricles and the great arteries leaving the heart (Aorta & Pulmonary trunk).**
- Function: **they allow the flow of blood from the ventricles to arteries.**

BLOOD CIRCULATION

CARDIO PULMONARY	SYSTEMIC
BETWEEN THE HEART AND THE LUNGS	BETWEEN THE HEART AND THE BODY
The right side of the heart (the right atrium & ventricle) receive deoxygenated blood	The left side of the heart (left atrium & ventricle) receive the oxygenated blood from the lungs
Blood is pumped to the lungs through the pulmonary Artery	Blood is pumped from the left ventricle to all body tissues through the Aorta and its systemic arteries
Gas exchange takes place in the lungs	The blood ultimately terminates in capillaries
It returns to the left side of the heart through 4 pulmonary veins	Deoxygenated blood circulates from the tissues to the capillaries, venules & veins back to the right atrium of the heart through the systemic veins

CORONARY CIRCULATION

- The heart has its own blood vessels that provide the myocardium with the oxygen and nutrients necessary to be able to pump blood to the body.
- The left and right coronary arteries branch off from the aorta and provide blood to the left and right sides of the heart.
- The coronary sinus is a vein on the posterior side of the heart that returns deoxygenated blood from the myocardium to the **vena cava**.
- Great, middle and small coronary veins drain into coronary sinus.
- Coronary sinus drains into **right atrium**.

<https://www.youtube.com/watch?v=xSnFf62GDBI>

Coronary Circulation

Why do Arteries have thick walls?

Arteries have much thicker walls than other blood vessels in order to withstand the higher blood pressure that propels oxygenated blood away from the heart

Blood vessels

Veins

The smallest veins are Venules

Thin walled

Many of them posses valves

Arteries

The smallest arteries are arterioles

Thick walled and do not have valves

Capillaries

Connect arterioles and venules

Help enable the exchange of water , oxygen and nutrients between blood and the tissues

Figure 9.12. Sections through an artery, capillary, and vein. At any given moment, about 30% of the blood in your systemic circulation will be found in the arteries, 5% in the capillaries, and 65% in the veins.

Arteries

- ❑ They transport blood from the heart and distribute it to the various tissues of the body through their branches.
- ❑ Carry oxygenated blood away from the heart.
 - **TWO EXCEPTIONS:**
 - **The pulmonary arteries.**
Carries deoxygenated blood from the heart to the lungs.
 - **The umbilical arteries.**
Supplies deoxygenated blood from the fetus to the placenta in the umbilical cord.

Anastomosis

Anastomosis: the connection between two structures (arteries, veins, or an artery and a vein)

Arterial anastomosis: is the joining of terminal branches of the arteries.

Function: It serves as a backup route if one of the branches is cut off (or blocked), allowing the blood to flow through other branches.

e.g. abdominal anastomosis (see picture)
intestinal arteries

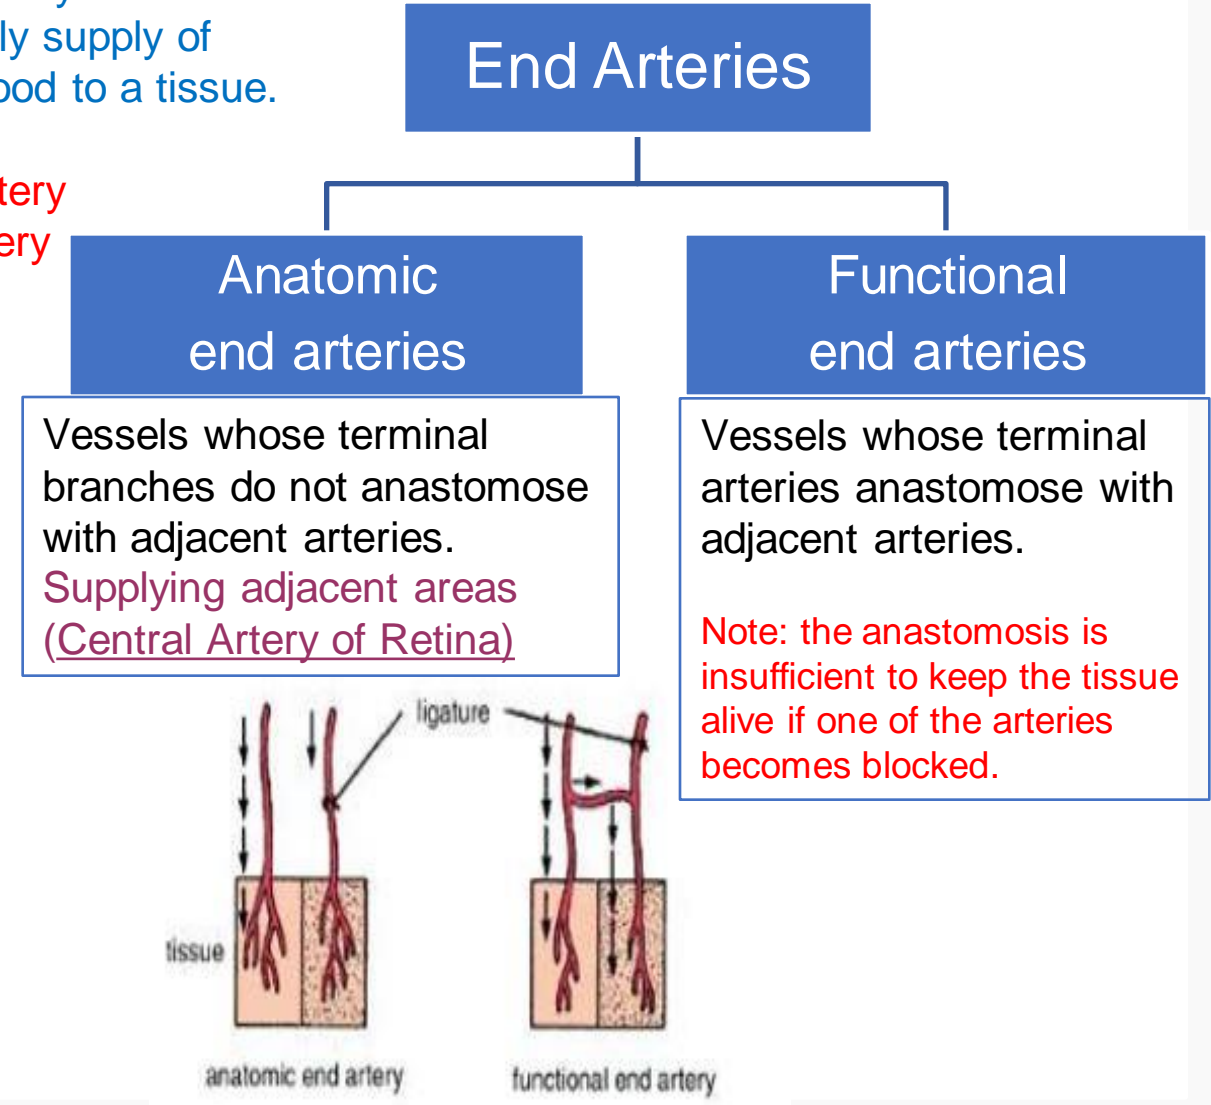

Arterial anastomosis

End Arteries

End Arteries: They are arteries that are the only supply of oxygenated blood to a tissue.

e.g. Splenic artery
Renal artery

Veins

- They transport blood back to the heart.
- The smaller venules (**Tributries**) unite to form larger veins which commonly join with one another to form Venous Plexuses.
- Carry deoxygenated blood towards the heart in all situations except two:

Pulmonary vein: carries the oxygenated blood from the lungs back to the heart (left atrium)

Umbilical vein: Carries the oxygenated blood from the placenta towards the fetus

Note: Veins do not branch they only unite.

Deep Veins (Venae Comitantes)

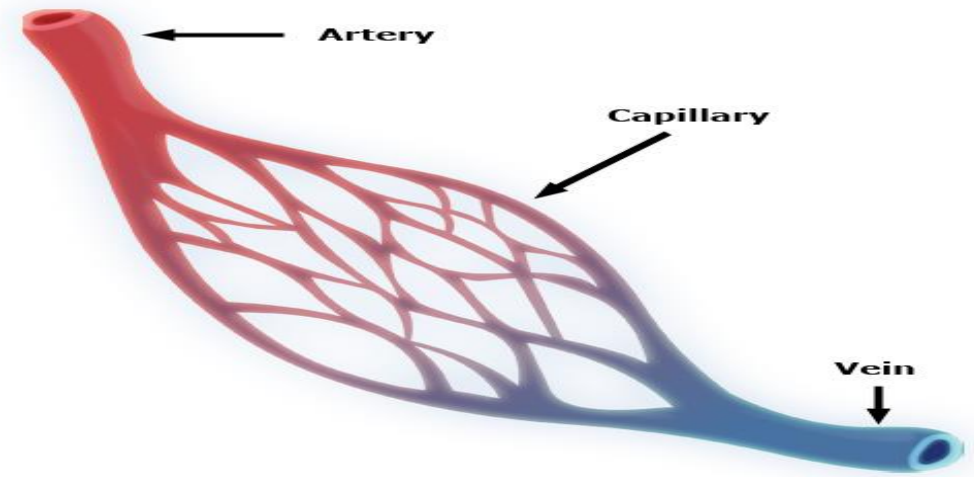

- They are two veins that accompany medium sized deep arteries.
- They are found in close to arteries so that the pulsations of the artery aid venous return.
- Venae comitantes are usually found with smaller arteries, especially those in the limbs. **Larger arteries do not have venae comitantes. They usually have a single, similarly sized vein.**

CAPILLARIES

- Microscopic vessels in the form of a network.

Function:

- They connect the **Arterioles** to the **Venules**.
- They help to enable the exchange of water, oxygen and many other nutrients between blood and the tissues.

© 2013 Encyclopædia Britannica, Inc.

ARTERIOVENOUS ANASTOMOSIS

- Direct connections between the arteries and veins **without the intervention of capillaries.**
- **Found in tips of the fingers and toes.**

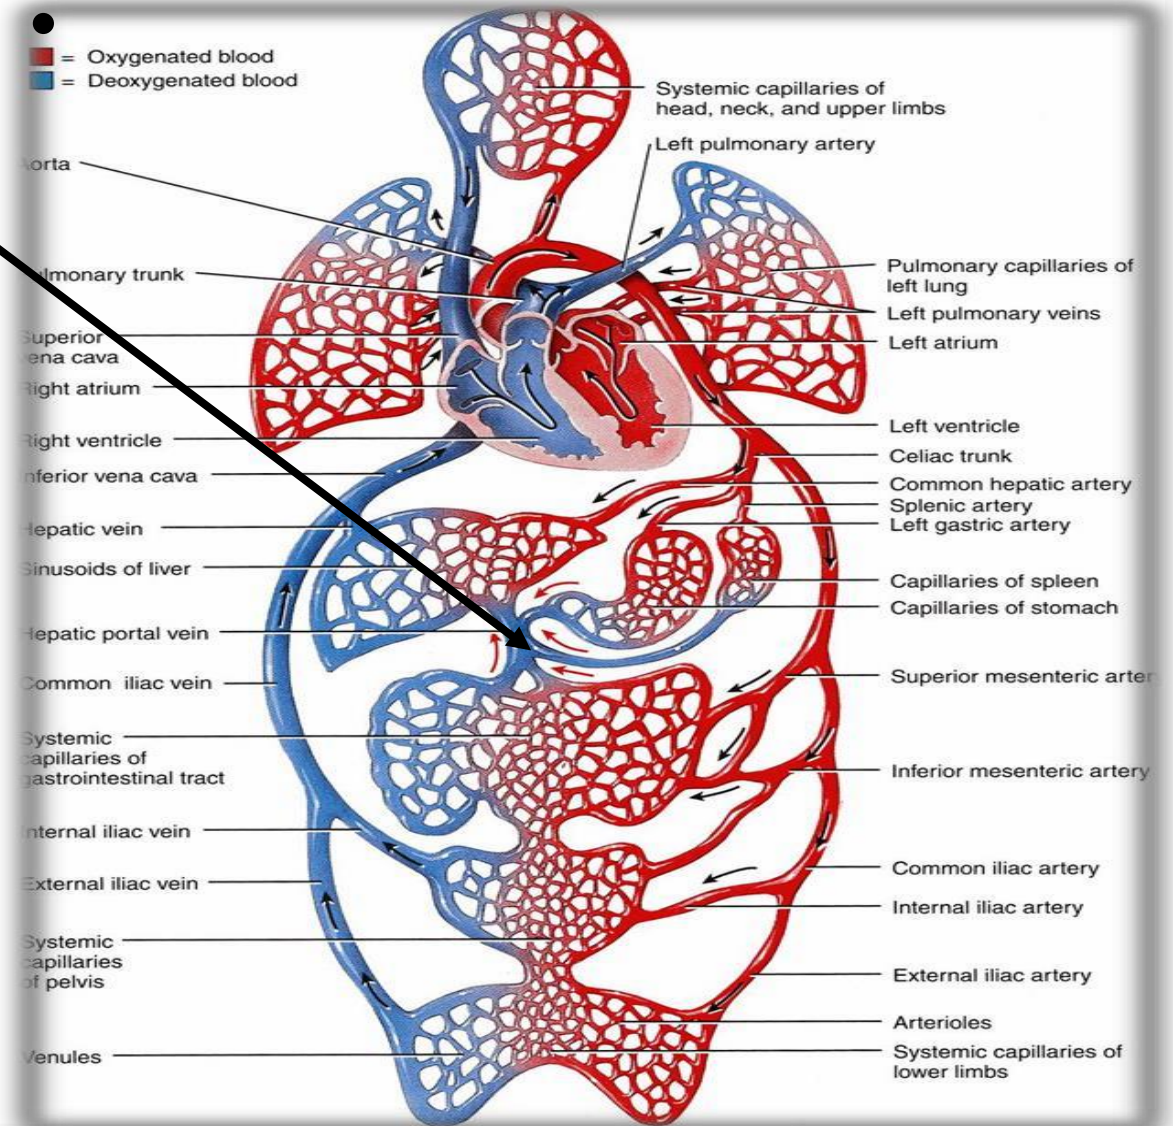

Portal circulation

Portal Venous System occurs when a capillary bed pools into another capillary bed through veins, **without first going through the heart.**

It is a system of vessels interposed between Two Capillary Beds.

Takes place in the liver and some endocrine glands (pituitary gland).

The purpose of **hepatic portal circulation** is to deliver blood from some parts of the gastrointestinal tract to the liver. In other words, blood is drained from the digestive organs (and the spleen, gall bladder, and pancreas) and the blood is then delivered to the liver.

Portal Circulation

- Veins leaving the gastrointestinal tract do not go direct to the heart.
- They pass to the Portal Vein.
- This vein enters the liver and breaks up again into veins of diminishing size which ultimately join capillary like vessels (Sinusoids).
- Venous blood enter 2nd capillary bed then to smaller veins that leave the liver through the hepatic vein.

Sinusoids are:
Thin walled blood vessels like capillaries.
Wider with irregular cross diameter.
Found in : liver, spleen, bone marrow, pituitary gland .

The sinusoids will get rid of the food by giving it to the liver cells which are surrounded by them .

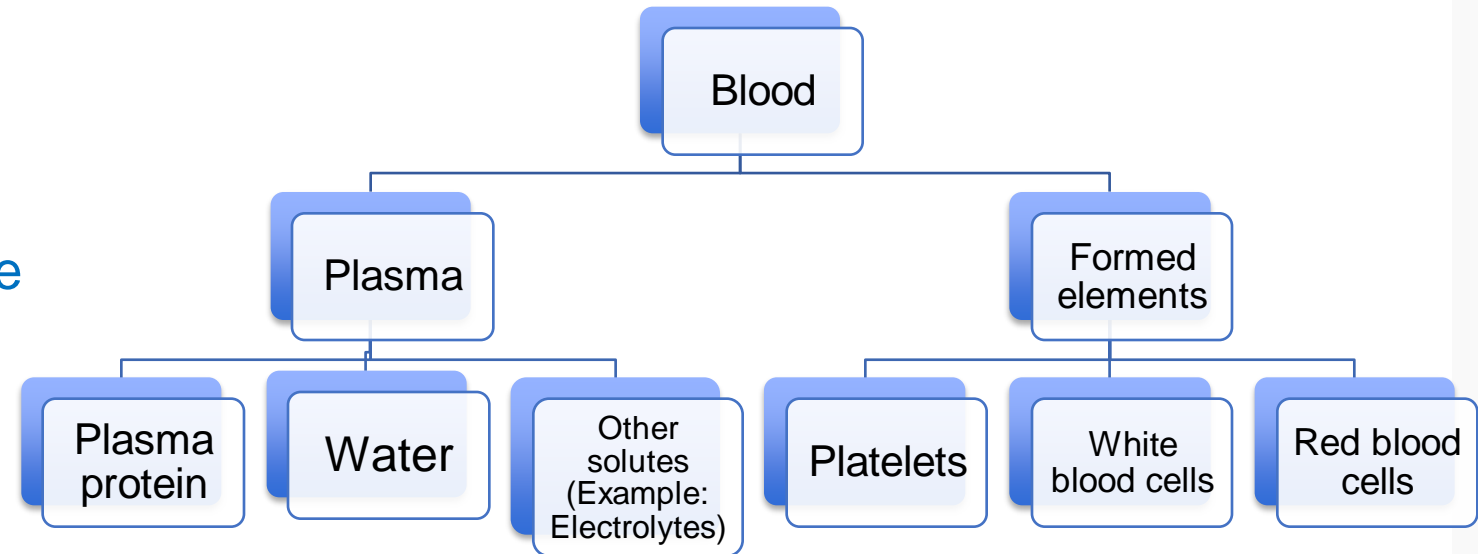

Why doesn't the blood go straight to the heart? Because it contains food with Venous blood (food can't go to the heart).

Structure and function of the heart

Structure	Function
Septum	Prevents mixing of oxygenated and deoxygenated blood
Aorta	Carries oxygenated blood
Pulmonary artery	Carries deoxygenated blood to the lung
Pulmonary vein	Carries oxygenated blood from the lung to the heart
Superior vena cava	Returns deoxygenated blood from head and arms to heart
Inferior vena cava	Returns deoxygenated blood from lower limbs and organs to heart

BLOOD

- Blood is the actual carrier of the oxygen and nutrients into arteries.
- Blood is made mostly of plasma, which is a yellowish liquid that is 90% water.
- Plasma contains also salts, glucose and other substances.
- Most important, plasma contains proteins that carry important nutrients to the body's cells and strengthen the body's immune system.
- Blood has main 3 types of blood cells that circulate with the plasma.

TYPES OF BLOOD CELLS

PLATELETS:

Helping the blood to clot. Clotting stops the blood from flowing out of the body when a vein or artery is broken. Platelets are also called **thrombocytes**.

RED BLOOD CELLS

Carry oxygen. A healthy adult has about 35 trillion of them. Red blood cells are also called **erythrocytes**.

WHITE BLOOD CELLS

These cells, which come in many shapes and sizes, are vital to the immune system **against infections**. When the body is fighting off infection, they increase. White blood cells are also called **leukocytes**.

Cardiovascular Diseases

HEART ATTACK

Occurs when blood flow to a part of the heart is blocked by a blood clot. If this clot cuts off the blood flow completely, the part of the heart muscle supplied by that artery begins to die. Most people survive their first heart attack and return to their normal lives to enjoy many more years of productive activity.

ISCHEMIC STROKE

Happens when a blood vessel that feeds the brain gets blocked, usually from a blood clot. When the blood supply to a part of the brain is shut off, brain cells will die.

HEMORRHAGIC STROKE

Occurs when a blood vessel within the brain bursts. The most likely cause is uncontrolled hypertension.

HEART FAILURE

It means the heart isn't pumping blood as well as it should. The heart keeps working, but the body's need for blood and oxygen isn't being met.

ARRHYTHMIA

This is an abnormal rhythm of the heart. The heart can beat too slow, too fast or irregularly.

HEART VALVE PROBLEMS

When heart valves don't open enough to allow the blood to flow through as it should.

Summary

- The cardiovascular system is a transporting system.
- It is composed of the heart and blood vessels.
- The heart is cone shaped, covered by pericardium and composed of four chambers.
- The blood vessels are the arteries, veins and capillaries.
- Arteries transport the blood from the heart.
- The terminal branches of the arteries can anastomose with each other freely or be anatomic or functional end arteries.
- Veins transport blood back to the heart.
- Capillaries connect the arteries to the veins.
- Sinusoids are special types of capillaries.
- The portal system is composed of two sets of capillaries.
- The veins from the GIT go first to the liver through the portal vein.
- Blood is the actual carrier of the oxygen and nutrients into arteries.
