# Health Care Associated Pneumonia

PROF. HANAN HABIB

Department of Pathology, Microbiology Unit, College Of Medicine, KSU

# Objectives

- Define the terms, pneumonia, community acquired pneumonia, health care associated pneumonia
- ( HCAP) and ventilator associated pneumonia (VAP).
- Describe the pathogenesis of the health care associated pneumonia (hospital associated pneumonia) and VAP.
- Classify HCAP according to the time of onset.

# Objectives

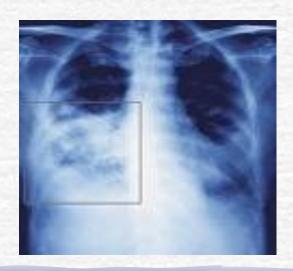

- Name the different causative bacterial agents.
- Classify and describe types of VAP.
- Recognize the ways by which VAP is prevented.
- Describe the different chemotherapeutic anti microbial agents used for the treatment of health care associated pneumonia.
- Evaluate response to treatment and recognize reasons for failure of treatment.

# Health Care Associated Pneumonia

Definition of Pneumonia:

Infection of the pulmonary Parenchyma

## PNEUMONIA can be:

- **A-Community acquired Pneumonia** acquired in the community, by community acquired organism, eg. *Streptococcus pneumoniae* usually susceptible to antibiotic.
- B-Health care associated pneumonia acquired 48-72 hours after admission to health care institutions eg. pneumonia caused by organisms in hospital which are usually resistant to antibiotics-eg. *Pseudomonas aeruginosa*

## **Definition**

- Nosocomial pneumonia: is defined as hospital associated pneumonia (HAP) or health care associated pneumonia (HCAP).
- Occurring at least 48 hours after admission and not incubating at the time of hospitalization.

# Health care associated Pneumonia

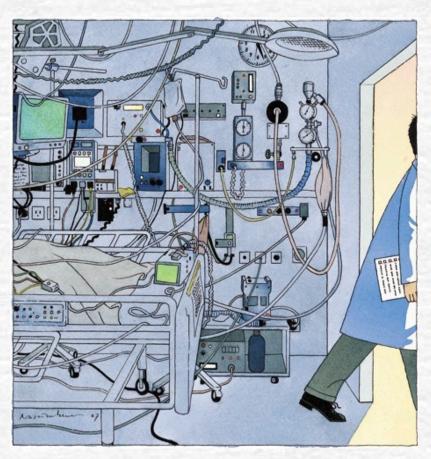

- A- Hospital Acquired Pneumonia(HAP)
- **B-** Ventilator Associated Pneumonia (**VAP**) in patients with assisted respiration for a period of 48 hours.

## Introduction

- Nosocomial pneumonia is the 2<sup>nd</sup> most common hospital-acquired infections after urinary tract infection. Accounting for 31 % of all nosocomial infections
- Nosocomial pneumonia is the leading cause of death from hospital-acquired infections.
- The incidence of nosocomial pneumonia is highest in **ICU** (intensive care unit) patients.

# ICU

## Introduction

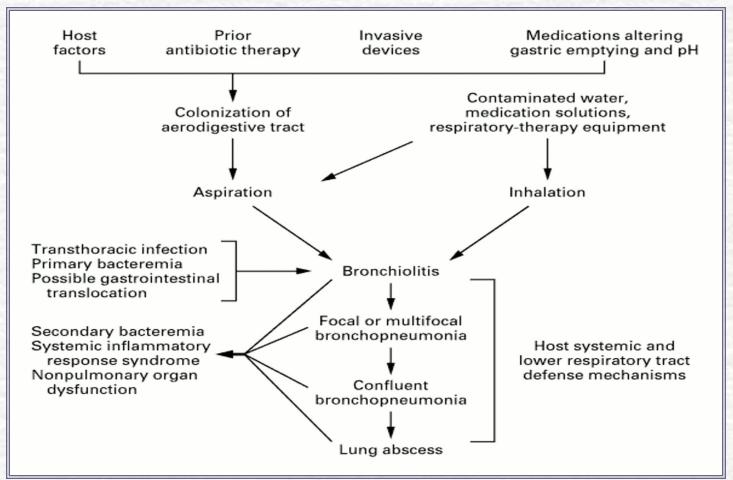

- The incidence of nosocomial pneumonia in ventilated patients is **10-fold higher** than non-ventilated patients
- The reported crude **mortality** for HAP is 30% to greater than 70%.

- For pneumonia to occur, at least one of the following **three conditions** must occur:
  - 1. Significant impairment of host defenses
  - 2. Introduction of a sufficient-size inoculum to overwhelm the host's lower respiratory tract defenses
  - 3. The introduction of highly virulent organisms into the lower respiratory tract
- Most common is microaspiration of oropharyngeal secretions colonized with pathogenic bacteria.

## Classification

- Early-onset nosocomial pneumonia:
  - Occurs during the first 4 days of admission.
  - Usually is due to *S. pneumoniae*, MSSA (Methicillin sensitive *S.aureus*), *H. Influenza*, or anaerobes.
- Late-onset nosocomial pneumonia:
  - OCCURS more than 4 days of admission.
  - More commonly by Gram negative organisms, especially: *P. aeruginosa, Acinetobacter, Enterobacteriaceae* (Klebsiella, Enterobacter, Serratia) or MRSA.

- most frequently particularly in patients with late-onset disease and in patients with serious underlying disease often already on broad-spectrum antibiotics.
- Prior use of broad-spectrum antibiotics and an immunocompromised state make resistant Gram-negative organisms more likely.

**P. aeruginosa** and **Acinetobacter** are common causes of late-onset pneumonia, particularly in ventilated patients.

- **S. aureus** is isolated in about 20~40% of cases and is particularly common in :
  - 1. Ventilated patients after head trauma, neurosurgery, and wound infection
  - 2. In patients who had received prior antibiotics or Prolonged care in ICU
- MRSA(methicillin resistant *S.aureus*) is seen more commonly in patients who:
  - Received corticosteroids
  - Undergone mechanical ventilation >5 days
  - Presented with chronic lung disease
  - Had prior antibiotics therapy

- Anaerobes are common in patients predisposed to aspiration .
- Ventilator associated pneumonia (VAP) with anaerobes occurred more often with oropharyngeal intubation than nasopharyngeal intubation.

# Ventilator-associated Pneumonia (VAP)

# Ventilator-associated Pneumonia (VAP)

#### Definition:

Nosocomial pneumonia that has developed in patient who are receiving mechanical ventilation.

#### Classification:

Early-onset: within 48-72 hours after tracheal

intubation, which complicates the

intubation process

Late-onset: after 72 hours

- Requires 2 important processes:
  - 1. Bacterial colonization of the aerodigestive tract
  - 2. Aspiration of contaminated secretion into the Lower airway
- Prevents mechanical clearance by cough and the mucociliary escalator.

### **Prevention for VAP**

The oral regimen (topical Gentamicin, Colistin, Vancomycin cream given every 6h for 3 weeks) treating oropharyngeal colonization could prevent VAP.

--- Prevention of VAP by oral decontamination

American journal of respiratory critical care medicine 2001 164:382-8

## **Preventions for VAP**

#### Non-pharmacologic strategies

- Effective hand washing and use of protective gowns and gloves
- Semirecumbent positioning
- Avoidance of large gastric volume
- Oral (non-nasal) intubation
- Continuous subglottic suctioning
- Humidification with heat and moisture exchanger
- Posture change

### **Preventions for VAP**

### **Pharmacologic strategies**

- Stress-ulcer prophylaxis
- Combination antibiotic therapy
- Prophylactic antibiotic therapy
- Chlorhexidine oral rinse
- Prophylactic treatment of neutropenic patients
- Vaccines

Most initial therapy is empiric because no pathogen is identified or results are not available when antimicrobial decisions are made in most patients.

- Initially be treated with a broadspectrum antibiotic regimen aimed at covering all likely bacterial pathogens
- This regimen should subsequently be narrowed, according to the result of culture.

- The pathogen may be influenced by coexisting illnesses, prior treatment, and length of hospitalization.
- The frequency of ICU-acquired *P. aeruginosa* carriage or colonization/infection was 23.4% at 7 days and 57.8% at 14 days.

---- Current opinion in infectious disease 2002, 15:387-94, copyright LWW

The mortality can be reduced with early appropriate empiric therapy.

(Form 30 % with appropriate therapy to more than 90 % with inappropriate therapy).

Guidelines by American Thoracic Society has divided patients into three groups, each with a set of probable pathogens.

Group 1: mild to moderate HAP with no risk factor

Group 2: mild to moderate HAP with risk factor

Group 3a: severe HAP, early-onset with no risk factor

Group 3b: severe HAP, late-onset or with risk factor

For mild-to-moderate HAP, monotherapy has been shown to be effective.

For **severe** HAP in which infection with resistant organisms is likely, combination therapy probably should be instituted until culture result are available.

- Patients with *S. aureus* infection, agents against this organism are necessary, including **Vancomycin** if MRSA is suspected.
- Linezolid is comparable with Vancomycin. The advantage of Linezolid is less possible nephrotoxicity.

---- current opinion in infectious disease 2002, 15:387-94, copyright LWW

- Combination of antipseudomonal drugs is controversial:
  - 1. Traditional:
    - antipseudomonal Beta-lactam with an Aminoglycoside. Synergy but potential nephrotoxicity.
  - 2. Another approach:
    - antipseudomonal Beta-lactam with a Fluoroquinolone.

No benefit of synergy but reduce concern of nephrotoxicity, and quinolone gets into the lungs at higher concentrations.

# Response to Therapy

If no clinical response is noted or deterioration occurs, we need to consider:

#### 1. Infectious causes:

Resistant pathogen

Superinfection

Unusual pathogens

Lung abscess

Extrapulmonary infection

#### 2. Noninfectious events:

Heart: congestive heart failure (CHF)

Lung: fibroproliferative acute respiratory distress syndrome (ARDS), pulmonary emboli, Atelectesis.
