

# Transport of Substances Through the Cell Membrane

---

**Dr. Maha Saja**

Physiology department,

Level 2,

Office 89,

Email: [msaja@ksu.edu.sa](mailto:msaja@ksu.edu.sa)

# Objectives

At the end of this session, the students should be able to:

- Describe the fluid mosaic model of membrane structure and function.
- Define permeability and list factors influencing permeability.
- Differentiate between passive and active transport mechanisms and give examples on each.
- Describe the different forms of passive transport and state the differences between them and the molecules transported by each type.
- Describe the different forms of active transport and state the difference between primary and secondary types giving examples for each in the human body.

**Study source for this lecture:**

(Guyton & Hall Textbook of Medical Physiology, 13<sup>th</sup> ed, Chapter 4)

# Structure of the Cell Membrane

---

# Structure of the Cell Membrane

- Cell membrane = plasma membrane.
- Thickness = 7.5-10 nm.
- Composed of:
  - Lipids (42%)
    - Phospholipids (25%)
    - Cholesterol (13%)
    - Other lipids (4%)
  - Proteins (55%)
  - Carbohydrates (3%)

# Structure of the Cell Membrane

- The cell membrane = a **lipid bilayer**.
- The most abundant lipid = phospholipids.
- A phospholipid molecule have two ends:
  - **Hydrophilic** (phosphate end)
  - **Hydrophobic** (fatty acid end)

# Structure of the Cell Membrane

## Membrane proteins

### Integral

Span the thickness of the cell membrane.

**Function as:**

1. Channels (or pores).
2. Carrier proteins.
3. Receptors.

### Peripheral

Are attached to one surface of the membrane.

**Function as:**

- Enzymes.
- Adhesion molecules.

# Channel vs. Carrier Proteins

**Channel proteins form open pores through which molecules of the appropriate size (e.g., ions) can cross the membrane.**

**Carrier proteins selectively bind the small molecule to be transported and then undergo a conformational change to release the molecule on the other side of the membrane.**

# Channel

# Carrier

# Structure of the Cell Membrane

## Function of CHO:

- Receptors.
- Cell-to-cell interaction.
- Immune reactions.

- Carbohydrates (CHOs) in the cell membrane are invariably attached to:
  - Proteins → Glycoproteins
  - Lipids → Glycolipids
- Carbohydrate molecules protrude to the outside of the cell forming a loose carbohydrate coat = “*glycocalyx*”

# The Fluid Mosaic Model of Plasma Membrane

# **Movement (Transport) of Substances Across the Cell Membrane**

---

# Substances that can Across the Cell Membrane

*Oil and water do not mix*

*Lipid soluble substances*

*Water soluble substances*

© 2007 Thomson Higher Education

**Cross freely by diffusion**

**Through membrane proteins**

*Alternative route*

# “*Selective Permeability*”

---

- The cell membrane is “*selectively permeable*” ... *what does this mean?*
- The membrane allows some substances to cross it but not others.
- It arises from the membrane’s structure.
- It controls the type & amount of substances entering and leaving the cell.

# Substances That Can Move Across the Cell Membrane

# Substances that Cannot Cross the Cell Membrane

*Will enter the cell through a trans-membrane protein carrier/transporter/channel*

# Transport Mechanisms

---

- The transport of material between body or cellular compartments can be divided into:
  1. *Passive Transport* = does not require energy.
  2. *Active Transport* = requires energy.

# Transport Mechanisms

## Passive Transport

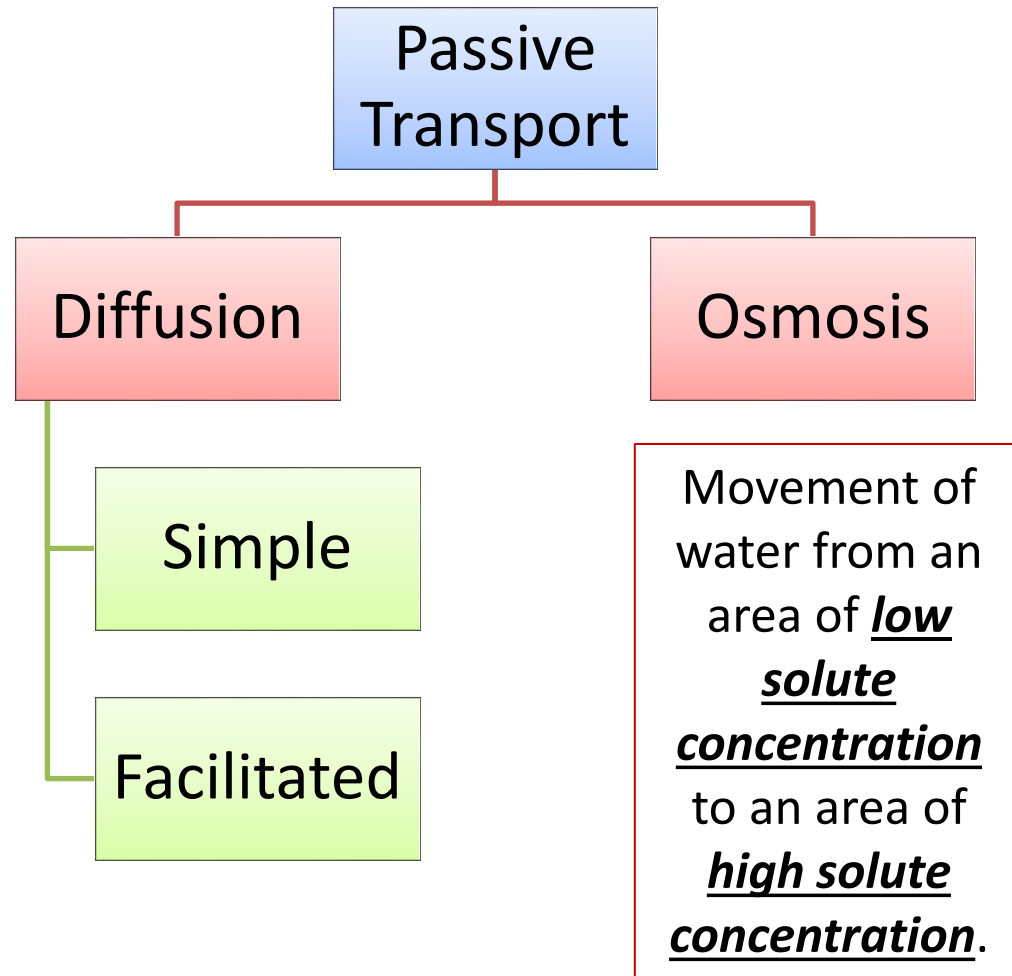

- Molecules move along their energy gradient.
- ***Does not require energy.***
- Types:
  - Simple Diffusion.
  - Facilitated Diffusion.
  - Osmosis.

## Active Transport

- Molecules move against their energy gradient.
- ***Requires energy.***
- Types:
  - Primary Active Transport.
  - Secondary Active Transport.

# Passive Transport Mechanisms

# Diffusion

- *Diffusion* = the random movement of substances down an energy gradient.
- This gradient can be:
  - Concentration gr.
  - Electrical gr.
  - Pressure gr.

# Diffusion

**TIME** →

# Types of Diffusion

## Diffusion

### Simple Diffusion

The movement of molecules through the intermolecular spaces or membrane openings (channels) *without* the necessity of *binding to a carrier protein* on the membrane.

### Facilitated Diffusion

*The transported molecule binds to a carrier protein* which then undergoes a conformational change allowing the molecule to pass through to the other side of the cell membrane.

The carrier *facilitates* passage of the molecule through the CM

# Types of Diffusion

1. **Lipid-soluble substances** (e.g. O<sub>2</sub>, CO<sub>2</sub>, and alcohol) → Pass through the interstices of the lipid bilayer.
2. **Water-soluble substances** (water, ions) → pass through channels that penetrate all the way through the CM.

- Also called “**Carrier-mediated diffusion**”.
- Diffusion of a substance is “**facilitated**” by the use of a specific carrier protein.
- Examples (glucose, amino acids).

# General Steps for Facilitated Diffusion

(Or any carrier-mediated transport)

**1. Solute-binding step**

**3. Release of solute on the opposite side of the membrane**

**2. Change in carrier conformation allowing solute to pass through**

# What is the difference between simple and facilitated diffusion?

## Simple diffusion

The rate of diffusion increases proportionately with the concentration of the diffusing substance.

## Facilitated diffusion

- The rate of diffusion increases proportionately with the concentration of the diffusing substance ***until it reaches a transport maximum ( $T_{max}$ )***.
- At  $T_{max}$ , an increase in the concentration of the diffusing substance ***does not*** increase the rate of diffusion.

# Why?

**$T_m$  = transport maximum** = the transport rate at which saturation occurs.

The rate at which molecules can be transported by facilitated diffusion **depends on:**

- 1. The number of solute-binding sites on the carrier.***
- 2. The rate at which the carrier protein molecule can undergo conformational change back and forth between its bound and unbound state.***

# Factors Affecting Rate of Diffusion

$$\text{Rate of diffusion} = P \times A (C_1 - C_2)$$

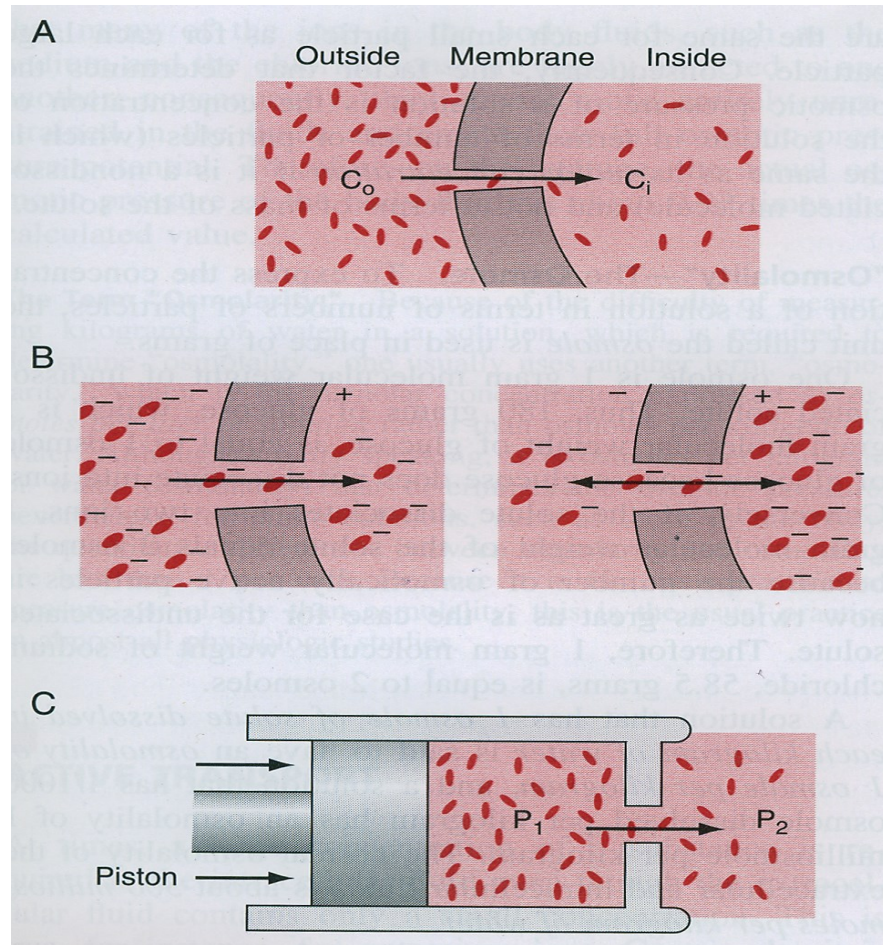

## 1. $P =$ Permeability coefficient.

- Temperature.
- Size of molecule.
- Solubility in lipids.
- Thickness of membrane.

## 2. $A =$ surface area.

## 3. $C_1 - C_2 =$ gradient difference:

- Concentration difference
- Electrical difference.
- Pressure difference.

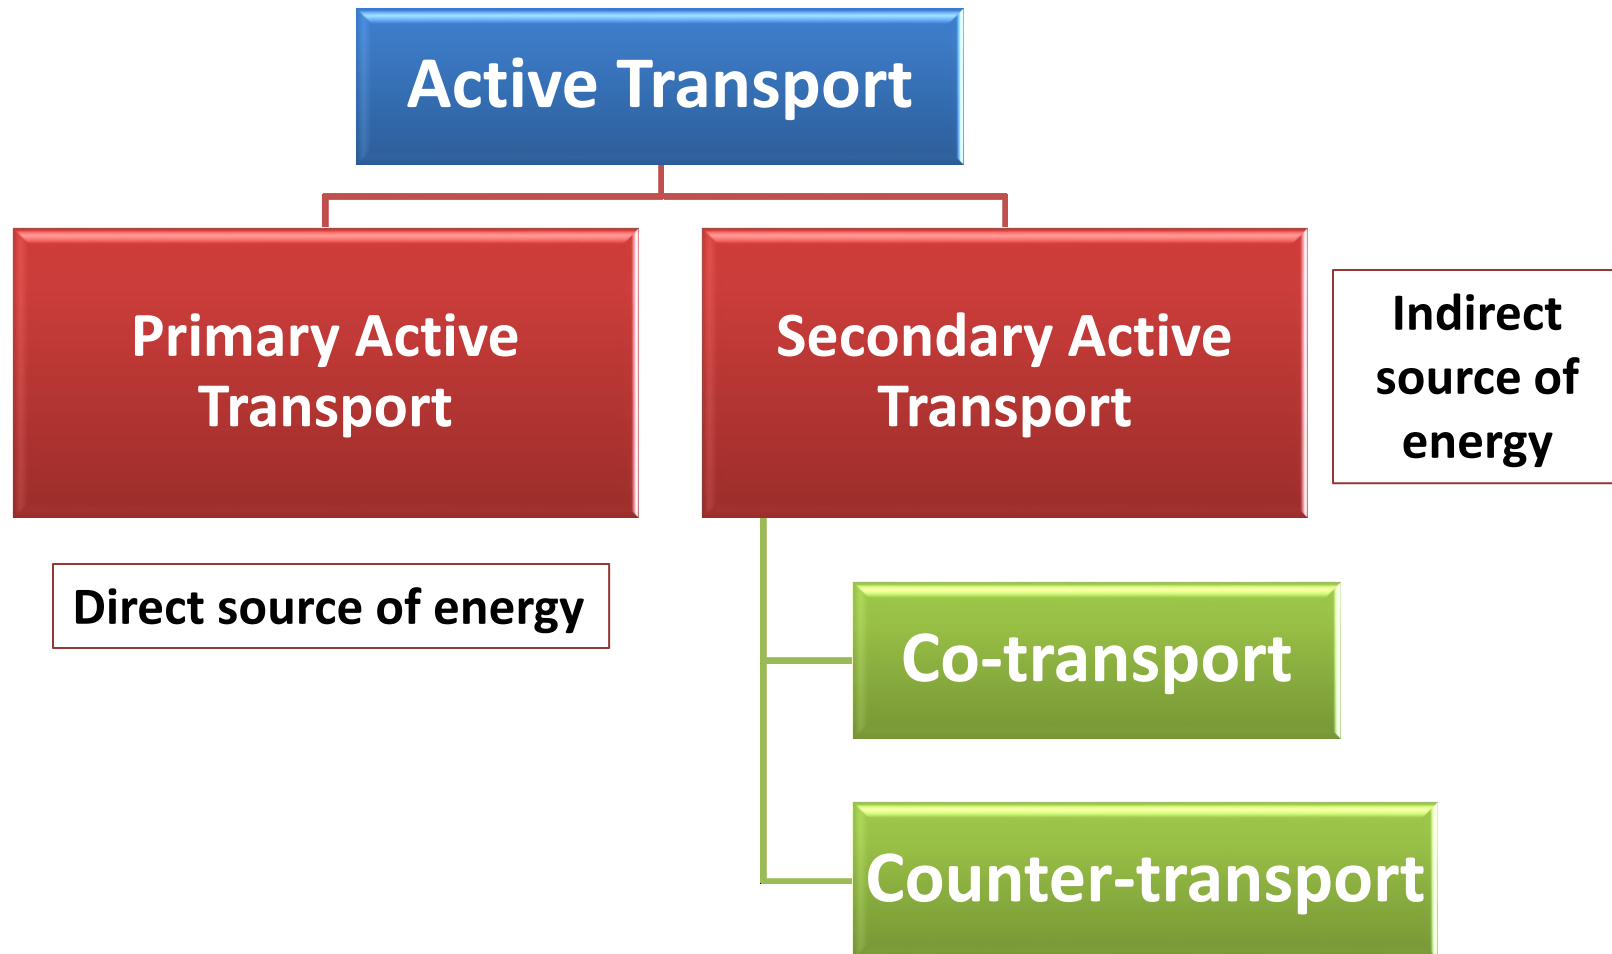

# Active Transport

- Occurs when a cell membrane moves molecules or ions **“uphill”** against a concentration gradient (or an electrical or pressure gradient).
- **Examples include:**
  - Ions like: sodium, potassium, calcium, iron, iodine, hydrogen ions.
  - Amino acids, glucose and other sugars.
- Requires **energy** and a **carrier protein**.

# Active Transport

*According to the source of energy used to fuel transport, it can be divided into;*

# Types of Active Transport

## Primary Active

- The energy is derived **directly** from breakdown of adenosine triphosphate (*ATP*) or some other high-energy phosphate compound.
- **3 main examples:**
  - Sodium-potassium ATPase pump.
  - Calcium ATPase pump
  - Hydrogen ATPase pump.

## Secondary Active

- The energy is derived **indirectly** by using the concentration or electrochemical gradient generated by a primary active transporter.

# Primary Active Transport

This pump functions by moving **3 molecules** of **sodium** **OUT** and **2 molecules** of **potassium** **INTO** the cell both against their concentration gradients.

## ***The importance of this pump:***

- Maintaining Na<sup>+</sup> and K<sup>+</sup> concentration differences across the cell membrane.
- Establishes a negative electrical voltage inside the cell.
- Is the basis for nerve signal transmission.

# Primary Active Transport

## H<sup>+</sup>-ATPase Pump

Present in:

- Parietal cells of stomach → secretion of HCl in the stomach.
- Intercalated cells of distal renal tubules → excretion of acids from the body.

Pumps H<sup>+</sup> out of the cell and into the lumen.

# Primary Active Transport

---

## Ca<sup>2+</sup> ATPase Pump

- Present in:
  - Sarcoplasmic reticulum in muscle cells
  - Mitochondria
  - Some cell membranes.
- Maintains low Ca<sup>2+</sup> concentration inside the cell.

# Secondary Active Transport (Co-transport)

*Derives energy indirectly... How?*

1. A  $\text{Na}^+\text{-K}^+$  pump maintains a concentration of  $\text{Na}^+$  that is higher outside the cell than inside.
2. Sodium ions move back into the cell through a transport protein that also moves glucose. The concentration gradient for  $\text{Na}^+$  provides energy required to move glucose against its concentration gradient.

# Secondary Active Transport (Counter-transport)

- Sodium Counter-transport of Calcium and Hydrogen Ions

Hall: Guyton and Hall Textbook of Medical Physiology, 12th Edition  
Copyright © 2011 by Saunders, an imprint of Elsevier, Inc. All rights reserved.

# Types of Secondary Active Transport

## Co-Transport

- When both substances are transported together in the same direction.
- **Examples;**
  - Na<sup>+</sup>-glucose co-transporter (PCT)
  - Na<sup>+</sup>-amino acid co-transporter (PCT)

## Counter-Transport

- When one substance is transported in the opposite direction to the other substance.
- **Examples;**
  - Na<sup>+</sup>-H<sup>+</sup> counter-transporter (PCT)
  - Na<sup>+</sup>-Ca<sup>2+</sup> counter-transporter

N.B. *PCT = proximal convoluted tubules* in the kidney
