

RESPIRATORY SYSTEM BLOCK

Pathology Practical

Prepared by:

- *Prof. Ammar Al Rikabi*
- *Dr. Sayed Al Esawy*

Head of Pathology Department: Dr. Hisham Al Khalidi

Objectives:

By the end of the practical sessions of the respiratory block, the medical students will be able to:

- Acquire the basic knowledge of the histopathological features of lobar pneumonia, bronchopneumonia, emphysema, pulmonary embolus and pulmonary infarction.
- Identify the gross appearance of bronchial asthma, bronchiectasis, bronchopneumonia, lobar pneumonia, bronchogenic carcinoma, squamous cell carcinoma and metastatic carcinoma of the lung, .

First Practical Session

- **Allergic Alveolitis**
- **Bronchial asthma**
- **Bronchiectasis**
- **Chronic Bronchitis**
- **Emphysema**
- **Lobar Pneumonia**
- **Bronchopneumonia**
- **Pulmonary Embolus & Infarction**

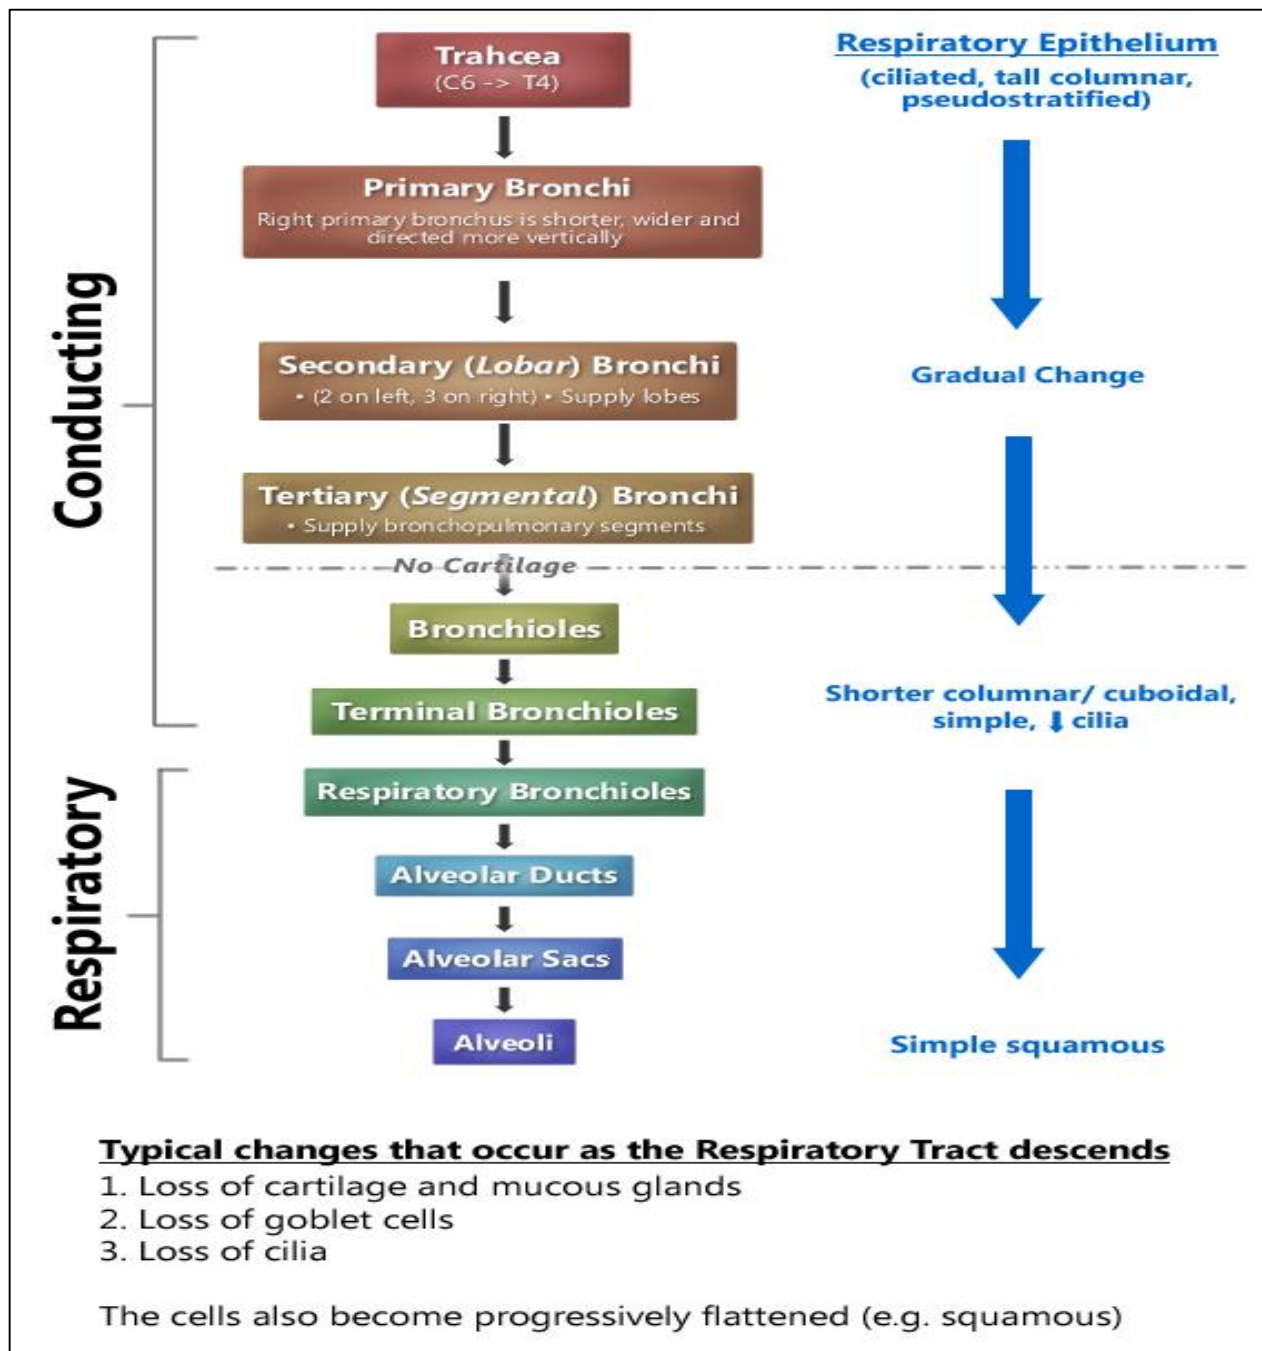

Anatomy of the Respiratory System

Lung Anatomy

- **Cartilage is present to the level of proximal bronchioles.**
- **Beyond terminal bronchiole gas exchange occurs.**
- **The distal airspaces are kept open by elastic tension in alveolar walls.**

Normal Histology of the Lungs

Microscopic section of normal lung showing terminal bronchiole (T) , respiratory bronchiole (R), alveolar duct (AD), alveolar sac (AS), and alveoli (A).

Normal Histology of the Lungs - Bronchiole

*This view shows a **BRONCHIOLE (left)** and **Blood Vessel (right)** in cross-section as well as numerous **ALVEOLI** in normal lung at 100X magnification.*

The bronchiole inner membrane is composed of pseudostratified columnar epithelial tissue. Portions of hyaline cartilage rings can also be seen outside of the bronchiole.

Normal Histology of the Lungs - Alveoli

Normal Alveoli: These oval-shaped alveoli expand with air during inspiration, have very thin epithelial walls and are surrounded by capillaries creating the respiratory membrane where gas exchange occurs between air and blood

Classification of Respiratory Diseases

1. Inflammatory lung diseases:

(Asthma, cystic fibrosis, & COPD)

2. Restrictive lung diseases:

(Allergic Alveolitis)

3. Obstructive lung diseases :

(Bronchial Asthma, Bronchiectasis, & (COPD- Ch. Bronchitis & Emphysema))

4. Respiratory tract infections:

-Upper resp. tract infection (sinusitis, tonsillitis, otitis media, pharyngitis & laryngitis)

-Lower resp. tract infection (Pneumonia & Bronchopneumonia , T.B.)

5. Malignant tumors (Squamous CC, adenocarcinoma, Large CC & Small CC)

6. Benign tumors (Pulmonary hamartoma, pulmonary sequestration)

7. Pleural cavity diseases (eg. Mesothelioma, effusion)

8. Pulmonary vascular diseases (Embolism, edema & hypertension)

9. Neonatal diseases (pulmonary hyperplasia.)

RESTRICTIVE LUNG DISEASES

ALLERGIC ALVEOLITIS

Restrictive Lung Disease

Fibrosing

Usual interstitial pneumonia (idiopathic pulmonary fibrosis)
Nonspecific interstitial pneumonia
Cryptogenic organizing pneumonia
Associated with collagen vascular disease
Pneumoconiosis
Associated with therapies (drugs, radiation)

Granulomatous

Sarcoidosis
Hypersensitivity pneumonia

Eosinophilic

Loeffler syndrome
Drug allergy-related
Idiopathic chronic eosinophilic pneumonia

Smoking-Related

Desquamative interstitial pneumonia
Respiratory bronchiolitis

Restrictive Lung Disease (Honeycomb lung) – Cut section

***“Honeycomb” lung. (extensive fibrosis from restrictive lung disease.
The gross appearance, as seen here in a patient with organizing diffuse alveolar damage***

Restrictive Lung Disease (Honeycomb lung) – LPF

Restrictive Lung Disease

Pulmonary fibrosis with extensive interstitial collagen deposition, minimal lymphocytic infiltrates, and residual airspace dilation.

Hypersensitivity Pneumonitis— Histopathology & Radiogram

This case of **extrinsic allergic alveolitis** shows **interstitial inflammation along alveolar ducts (bronchiolocentric distribution or peribronchiolar)**. The inflammation is **diffuse, lacks nodularity, and manifests radiologically as a ground-glass pattern**

Hypersensitivity Pneumonitis (HP)

Interstitial bronchiolocentric pneumonitis (Extrinsic allergic alveolitis) with lymphocytes, plasma cells and foamy macrophages in alveolar space and terminal airways . Interstitial fibrosis, obliterative bronchiolitis and intra-alveolar exudate . Nodules of organizing fibroblasts, histiocytes with Interstitial noncaseating granulomas and other inflammatory cells

Hypersensitivity Pneumonitis (HP)

Interstitial fibrosis, lymphocyte infiltration in the alveolar wall, mainly collagen fibers hyperplasia, especially in the bronchioles due to their respective muscle fibers and endothelial cell proliferation and thickening

OBSTRUCTIVE LUNG DISEASES

- 1. Bronchial Asthma**
- 2. Bronchiectasis**
- 3. COPD :**
(Chronic Bronchitis & Emphysema)

1. BRONCHIAL ASTHMA

BRONCHIAL ASTHMA - Anatomy

Bronchial Asthma: Inflammation of the airways causes airflow into and out of the lungs to be restricted. The muscles of the bronchial tree become tight and the lining of the air passages swells, reducing airflow and producing the characteristic wheezing sound

BRONCHIAL ASTHMA - LPF

Between the bronchial cartilage at the right and the bronchial lumen filled with mucus at the left is a submucosa widened by smooth muscle hypertrophy, edema, and inflammation (mainly eosinophils). These are changes of bronchial asthma. The peripheral eosinophil count or the sputum eosinophils can be increased during an asthmatic attack.

BRONCHIAL ASTHMA - LPF

Bronchus from a fatal case of bronchial asthma in a 4-year-old child. There is partial plugging of the lumen, an intense inflammatory infiltrate and vascular congestion.

BRONCHIAL ASTHMA - HPF

Changes of bronchial asthma: the numerous eosinophils are prominent from their bright red cytoplasmic granules in this case of bronchial asthma

2. BRONCHIECTASIS

Diagram of Normal & Bronchiectatic Bronchus

In Bronchiectasis, mucus production increases, the cilia are destroyed or damaged, and areas of the bronchial wall become chronically inflamed and are destroyed.

Bronchiectasis – Gross pathology & Colored X-ray

Permanent dilatation of bronchi and bronchioles caused by destruction of muscle and elastic tissue resulting from or associated with chronic necrotizing infection -Markedly distended peripheral bronchi.

Bronchiectasis – Gross pathology

Bronchiectasis occurs when there is obstruction or infection with inflammation and destruction of bronchi so that there is permanent dilation.

Bronchiectasis – Gross pathology

Bronchiectasis is seen here. The repeated episodes of inflammation can result in scarring, which has resulted in fibrous adhesions between the lobes. Fibrous pleural adhesions are common in persons who have had past episodes of inflammation of the lung that involve the pleura.

Bronchiectasis – LPF

Section of a dilated bronchus with florid acute on chronic inflammation of the bronchial wall and surrounding interstitial fibrosis.

Bronchiectasis – HPF

Chronic inflammation, ulceration of bronchial wall, ossification of bronchial cartilage, thickened pleura . Variable inflammation and fibrosis of alveoli

Chronic Obstructive Pulmonary Diseases (COPD)

also known as

**Chronic Obstructive Lung Disease (COLD),
Chronic Obstructive Airway Disease (COAD),
Chronic Obstructive Respiratory Disease (CORD)**

Include:

3. Chronic Bronchitis

4. Emphysema,

a pair of commonly co-existing diseases of the lungs in which the airways narrow over time.

3. CHRONIC BRONCHITIS

Normal vs Chronic bronchitis

Normal

Chronic Bronchitis

Chronic Bronchitis - LPF

Inflammatory infiltrate in bronchial walls is composed of lymphocytes and plasma cells. In the lumen desquamated epithelial cells (catarrhal inflammation) .In mucosa often occurs mataplasia of cylindric cilliated epithelium into multilayered squamous epithelium. Goblet cells are hyperplastic, hyperplastic are also the sero-mucous glands in the submucosal layer. Muscularis mucosae is hypertrophic

Chronic Bronchitis - LPF

Early - hypersecretion of mucus in large airways with hypertrophy of submucosal glands in tracheobronchial tree . Later - increase in goblet cells in small airways contributes to excessive mucus production and airway obstruction .

Chronic Bronchitis - HPF

Chronic inflammatory infiltrates range from absent to prominent. Increased percentage of bronchial wall occupied by submucosal mucous glands, as measured by Reid index; this directly correlates with sputum production, variable dysplasia, squamous metaplasia, bronchiolitis obliterans.

4. EMPHYSEMA

Emphysema – Clinical Features

Complications:

- **Pulmonary hypertension.**
- **Cor pulmonale.**
- **Respiratory failure.**
- **Pneumothorax.**

Emphysema patient (so-called -pink puffers) exhibit dyspnea without significant hypoxemia and tend to be thin, to have hyperinflated lung fields at total lung capacity, and to be free of signs of right heart failure

Normal Lung

Emphysema

A

Normal Lung

B

Emphysema

Emphysema – Gross Anatomy

The chest cavity is opened at autopsy to reveal numerous large bullae apparent on the surface of the lungs in a patient dying with emphysema. Bullae are large dilated airspaces that bulge out from beneath the pleura.

Emphysema – Gross pathology

Dilated airspaces in emphysematous lung. Although there tends to be some scarring with time because of superimposed infections, the emphysematous process is one of loss of lung parenchyma, not fibrosis

Bullous Emphysema – Gross pathology

A bulla is defined as an emphysematous space larger than 1 cm.

Centrilobular Emphysema – Gross pathology

Centrilobular emphysema : Fixed, cut surface of a lung shows multiple cavities lined by heavy black carbon deposits characteristic of smoking.

Panacinar Emphysema – LPF

- **Enlarged air spaces/alveolar spaces.**
- **Destruction of some alveolar septi.**

Panacinar Emphysema – LPF

Some of the alveolar septae are ruptured and the ruptured septa project within air spaces on the form of spurs.

Panacinar Emphysema - HPF

Destruction of tissue leaves emphysematous spaces with little surface area, few capillaries, and large air spaces. Large vessel at lower left

LOWER RESPIRATORY TRACT INFECTIONS

1. Lobar Pneumonia

Lobar Pneumonia - Gross pathology

Lobar Pneumonia - Gross pathology

A closer view of the lobar pneumonia demonstrates the distinct difference between the upper lobe and the consolidated lower lobe.

Lobar Pneumonia : X - Ray

Lobar Pneumonia of the right Lower lobe

Lobar Pneumonia of the right middle lobe

A localised focus of consolidation caused by lobar pneumonia can be seen in both X-ray films taken from 2 different patients .

Lobar Pneumonia - Histopathology

- * **Congestion (first 2 days)**
- * **Red hepatisation (fibrinous alveolitis) (2nd to 4th day)**
- * **Grey hepatisation (leukocytic alveolitis) (4th to 8th day)**
- * **Resolution (after 8th day)**

Lobar Pneumonia - LPF

All the alveoli are filled with fibrinous exudate containing fibrin threads, polymorphs, macrophages and red cells. Alveolar walls are congested. Pleura is covered by fibrinous exudate.

Lobar Pneumonia - LPF

the alveoli are filled with fibrinous exudate containing fibrin threads, polymorphs, macrophages and red cells

Lobar Pneumonia - HPF

Alveoli filled with fibrinous exudate containing fibrin threads, polymorphs, macrophages and red cells. and thickened alveolar wall

2. Bronchopneumonia

Bronchopneumonia – Gross pathology

- ***In Lobular Pneumonia the consolidated areas very closely match the pattern of lung lobules (hence the term "lobular" pneumonia).***
- ***Bronchopneumonia is classically a "hospital acquired" pneumonia seen in persons already ill from another diseases e.g. DM , old age , immune deficiency process.***

Bronchopneumonia – Cut section

This bronchopneumonia is more subtle, but there are areas of lighter tan consolidation. The hilum is seen at the lower left with radiating pulmonary arteries and bronchi

Bronchopneumonia – X-Ray

This radiograph demonstrates patchy infiltrates consistent with a bronchopneumonia from a bacterial infection.

Bronchopneumonia – Histopathology

Bronchopneumonia (Lobular pneumonia) is an acute exudative inflammation of the lungs characterised by foci of consolidation surrounded by normal parenchyma. Usually, bronchopneumonia affects one or more lobes and is bilateral.

Bronchopneumonia – LPF

Section of the lung shows foci of inflammatory consolidation surrounding bronchioles: Bronchioles are filled with an inflammatory purulent exudate and show ulceration of mucosa, focal inflammation and necrosis of walls . Surrounding lung parenchyma shows congestion and edema

Bronchopneumonia – MPF

At high magnification, the alveolar exudate of mainly neutrophils is seen. The surrounding alveolar walls have capillaries that are dilated and filled with RBC's. Such an exudative process is typical for bacterial infection. This exudate gives rise to the productive cough of purulent yellow sputum seen with bacterial pneumonias

PULMONARY EMBOLUS AND INFARCTION

Thromboembolism in the Lung – Gross

A large pulmonary thromboembolus is seen in the pulmonary artery to the left lung. Such thromboemboli typically originate in the leg veins or pelvic veins of persons who are immobilized

Thromboembolism in the Lung – Gross

Large thromboemboli can cause death. Medium sized thrombemboli (blocking a pulmonary artery to a lobule or set of lobules) can produce the lesion seen here -a hemorrhagic pulmonary infarction which is a wedge-shaped and based on the pleura.

Pulmonary embolus and infarction in the Lung

A Longitudinal transection of a lung showing a wedge shaped peripheral hemorrhagic infarction .

A thrombus is seen in a major branch of pulmonary artery (arrow head) .

Pulmonary Embolus with infarction – CT scan

CT scan - white arrows show pulmonary embolus with lung infarction

Pulmonary artery thromboembolus - LPF

Microscopic appearance of a pulmonary thromboembolus in a large pulmonary artery. There are interdigitating areas of pale pink and red that form the "lines of Zahn" characteristic for a thrombus.

Small pulmonary artery thromboembolus - HPF

A small peripheral pulmonary artery thromboembolus. If these small PE are showered into the pulmonary circulation at once or over a period of time will lead to pulmonary hypertension.

Fat Embolism in the Lung - HPF

The rounded holes that appear in the vascular spaces here in the lung are fat emboli. Fat embolization syndrome occurs most often following trauma with fracture of long bones that releases fat globules into the circulation which are trapped in pulmonary capillaries

SECOND PRACTICAL

1. TUBERCULOSIS

2. CANCER OF THE LUNG

TUBERCULOSIS

- **Epithelioid and giant cell Granuloma, Ghon's complex or caseation is present**
- **Complications of TB are:**
 - Amyloidosis ,
 - Tuberculous pneumonia
 - Miliary tuberculosis
 - Tuberculous meningitis
 - Addison disease .

Pulmonary TB – Caseous Necrosis – Gross

On closer inspection, the granulomas have areas of caseous necrosis. This pattern of multiple caseating granulomas primarily in the upper lobes is most characteristic of secondary (reactivation) tuberculosis

Pulmonary TB – Caseous Necrosis – Gross

Extensive caseation and the granulomas involve a larger bronchus causing soft, necrotic center to drain out and leave behind a cavity. Cavitation is typical for large granulomas with TB. Cavitation is more common in the upper lobes.

Pulmonary TB - Ghon's Complex – Gross Pathology

The Ghon's complex is seen here at closer range. Primary tuberculosis is the pattern seen with initial infection with tuberculosis in children. Reactivation, or secondary tuberculosis, is more typically seen in adults.

Miliary TB of the Lungs

- **Miliary TB can occur when TB lung lesions erode pulmonary veins or when extrapulmonary TB lesions erode systemic veins.**
- **This results in hematogenous dissemination of tubercle bacilli producing myriads of 1-2 mm. lesions throughout the body in susceptible hosts.**
- **Miliary spread limited to the lungs can occur following erosion of pulmonary arteries by TB lung lesions.**

Miliary TB of the Lungs – Cut section

This is a "miliary" pattern of granulomas because there are a multitude of small tan granulomas, about 2 to 4 mm in size, scattered throughout the lung parenchyma. The miliary pattern gets its name from the resemblance of the granulomas to millet seeds.

Miliary TB of the Lungs – X-Ray

Miliary tuberculosis is most prominent in the liver, bone marrow, spleen, adrenals, meninges, kidneys, fallopian tubes, and epididymis.

Complications:

Amyloidosis

TB meningitis

TB spleen

Fallopian tube TB

TB epididymitis.

Etc...

This chest x-ray shows a patient with miliary TB.

Tuberculous Granulomas - LPF

At low magnification, this micrograph reveals multiple granulomas. Granulomatous disease by chest radiograph appear as reticulonodular densities.

Tuberculous Granulomas - HPF

Well-defined granulomas are seen here. They have rounded outlines. The one toward the center of the photograph contains several Langhan's giant cells. Granulomas are composed of transformed macrophages called epithelioid cells along with lymphocytes, occasional PMN's, plasma cells, and fibroblasts

Pulmonary TB - Granuloma with central early necrosis

Epithelioid Granuloma with caseation.

Tuberculous Granulomas - HPF

The edge of a granuloma is shown here at high magnification. At the upper is amorphous pink caseous material [1] composed of the necrotic elements of the granuloma as well as the infectious organisms. This area is ringed by the inflammatory component [2] with epithelioid cells, lymphocytes, and fibroblasts.

Epithelioid & Giant cell Granulomas in *Tuberculosis*

At high magnification, the granuloma demonstrates that the epithelioid macrophages are elongated with long, pale nuclei and pink cytoplasm. The macrophages organize into committees called giant cells. The typical giant cell for infectious granulomas is called a Langhan's giant cell and has the nuclei lined up along one edge of the cell

Acid Fast bacilli of Mycobacterium TB in the Lung

*A stain for **Acid Fast Bacilli** is done (**AFB** stain) to find the mycobacteria .
The mycobacteria stain as red rods, as seen here at high magnification.*

LUNG CARCINOMA

TWO TYPES OF LUNG CARCINOMA

- **NON-SMALL CELL CARCINOMA**
 1. **SQUAMOUS CELL CARCINOMA**
 2. **ADENOCARCINOMA**
 3. **LARGE CELL CARCINOMA**
- **SMALL CELL CARCINOMA**

The NON-small cell cancers behave and are treated similarly, the SMALL cell carcinomas are WORSE than the non-small cell carcinomas, but respond better to chemotherapy, often drastically!

1. Squamous Cell Carcinoma of the lung

- **Most commonly found in men and correlated with smoking.**
- **Pathology: more differentiated, more cytoplasm, keratin whorls.**
- **Transforms from carcinoma in situ.**
- **Grading is based on the amount of keratin & cytoplasm.**

Squamous Cell Carcinoma of the Lung - Gross

This is a squamous cell carcinoma of the lung that is arising centrally in the lung (as most squamous cell carcinomas do). It is obstructing the right main bronchus. The neoplasm is very firm and has a pale white to tan cut surface.

Squamous Cell Carcinoma of the Lung - Gross

This is a larger squamous cell carcinoma in which a portion of the tumor demonstrates central cavitation, probably because the tumor outgrew its blood supply.

Squamous Cell Carcinoma of the Lung – CT scan

This chest CT scan view demonstrates a large squamous cell carcinoma of the right upper lobe that extends around the right main bronchus and also invades into the mediastinum and involves hilar lymph nodes.

Squamous Cell Carcinoma of the Lung - HPF

Microscopic appearance of squamous cell carcinoma with nests of polygonal cells with pink cytoplasm and distinct cell borders. The nuclei are hyperchromatic and angular.

Squamous Cell Carcinoma of the Lung - HPF

In this squamous cell carcinoma at the upper left is a squamous eddy with a keratin pearl. At the right, the tumor is less differentiated and several dark mitotic figures are seen

Squamous Cell Carcinoma of the Lung - HPF

Neoplastic squamous cells show pleomorphism, hyperchromatism, individual cell keratinization, mitoses and areas of necrosis.

Squamous Cell Carcinoma of the Lung - HPF

The pink cytoplasm with distinct cell borders and intercellular bridges characteristic for a squamous cell carcinoma of the lung

2. Adenocarcinoma of the lung

- The most common type of lung cancer, making up 30-40% of all cases.
- Glandular differentiation by tumor cells and 80% of those cells produce mucin.
- Not as strongly associated with a smoking history as compared to Squamous or Small Cell Carcinomas
- Adenocarcinoma in situ - called bronchoalveolar carcinoma
- Early and distant metastases
- Genetic mutations: EGFR (Epithelial Growth Factor Receptor) gene mutation and Alk (Alkaline Phosphatase enzyme) gene mutation.

Adenocarcinoma of the Lung – Gross

A peripheral adenocarcinoma of the lung. Adenocarcinomas and large cell anaplastic carcinomas tend to occur more peripherally in lung. Adenocarcinoma is the one cell type of primary lung tumor that occurs more often in non-smokers and in smokers who have quit.

Adenocarcinoma of the Lung

X-Ray

A peripheral adenocarcinoma of the lung appears in this chest radiograph of an elderly non-smoker woman.

CT scan

Peripheral right lung nodular mass.

Adenocarcinoma of the Lung – LPF

Microscopically, the **Adenocarcinoma in Situ** (Previously named **Bronchioloalveolar Carcinoma**) is composed of columnar cells that proliferate along the framework of alveolar septae. The cells are well-differentiated.

Adenocarcinoma of the Lung – HPF

- ***Malignant glands lined by cells showing irregular nuclei and prominent nucleoli.***
- ***Desmoplastic fibro-inflammatory tissue surrounding the malignant gland.***

Adenocarcinoma of the Lung – HPF

Differentiated malignant glands lined by pleomorphic and hyperchromatic malignant cells showing conspicuous nucleoli

3. Large Cell Carcinoma of the lung

- **Can be a neuroendocrine carcinoma. Probably represents undifferentiated SCC and adenocarcinomas.**
- **Large nuclei, prominent nucleoli.**
- **Variation in size and shape.**
- **Nuclei normally do not touch due to more cytoplasm.**
- **Moderate amount of cytoplasm.**
- **Early and distant metastases, sometimes cavitating.**

Large Cell Carcinoma of the Lung – Gross

Undifferentiated Large Cell Carcinoma of the Lung – Gross

Large Cell Carcinoma of the Lung – HPF

Pleomorphic carcinoma of lung (large cell and giant cell subtype). It shows mixed composition of large cell carcinoma and pleomorphic multinucleated giant cells (arrows). (H and E, ×200)

Large Cell Carcinoma of the Lung – HPF

This section from lower respiratory tract shows neoplastic cells with abundant pale eosinophilic cytoplasm and a surrounding infiltrate of inflammatory cells

Large Cell Carcinoma of the Lung – HPF

This section shows neoplastic cells with abundant pale eosinophilic cytoplasm and pleomorphic multinucleated giant cells

Small cell carcinoma of the lung

- **Highly Malignant Tumor.**
- **Cells are small, with scant cytoplasm, ill-defined borders, finely granular chromatin (salt & pepper pattern) and absent or inconspicuous nucleoli.**
- **High mitotic count and often extensive necrosis.**
- **Typically not graded as all SCLC are considered High Grade.**
- **Very strong relationship with smoking.**
- **Often lead to paraneoplastic syndromes.**

Small Cell Carcinoma of the Lung “Oat cell” – Gross

Arising centrally in this lung and spreading extensively is a small cell anaplastic (oat cell) carcinoma. The cut surface of this tumor has a soft, lobulated, white to tan appearance. The tumor seen here has caused obstruction of the main bronchus to left lung so that the distal lung is collapsed

Small Cell Carcinoma of the Lung “Oat cell” – Gross

Oat cell carcinoma which is spreading along the bronchi. The speckled black rounded areas represent hilar lymph nodes with metastatic carcinoma

Small Cell Carcinoma of the Lung “Oat cell” : X-Ray

This chest radiograph demonstrates a mass lesion in the right upper lobe. This was an oat cell carcinoma (yellow arrow). It obstructed the right main bronchus, leading to atelectasis on the right, evidenced by a raised right hemidiaphragm. The patient aspirated gastric contents, producing a diffuse pneumonia (blue arrow) on the left (since aspirated material could not pass the obstruction on the right).

Small Cell Carcinoma of the Lung “Oat cell” – HPF

This is the microscopic pattern of a small cell anaplastic (oat cell) carcinoma in which small dark blue cells with minimal cytoplasm are packed together in sheets.

Small cell carcinoma “Oat cell” of the lung - HPF

Section of the tumor shows clusters of malignant cells which are small , round , ovale , or spindle shaped with prominent nuclear molding , finely granular nuclear chromatin (salt and pepper pattern) , high mitotic count and focal necrosis

Metastatic tumours of the lung

METASTATIC TUMORS

- **LUNG** is the **MOST COMMON** site for all metastatic tumors, regardless of the site of origin.
- It is the site of **FIRST CHOICE** for metastatic sarcomas for purely anatomic reasons !

Metastatic Tumors of the Lung – Gross & X-ray

Multiple variably-sized masses are seen in all lung fields. These tan-white nodules are characteristic for metastatic carcinoma. Metastases to the lungs are more common even than primary lung neoplasms

Chest X-ray showing multiple cannon ball opacities in both lung fields.

Metastatic Tumors of the Lung – Gross & CT scan

Here are larger but still variably-sized nodules of metastatic carcinoma in lung.

CT Lung shows Cannonball Metastases-large, hematogenously spread metastatic lesions in the lungs of varying sizes most often from colon, breast, renal, thyroid primaries

Metastatic Tumors of the Lung – LPF

A nest of metastatic infiltrating ductal carcinoma from breast is seen in a dilated lymphatic channel in the lung. Carcinomas often metastasize via lymphatics.

Metastatic Tumors of the Lung – LPF

A focus of metastatic carcinoma from breast is seen on the pleural surface of the lung. Such pleural metastases may lead to pleural effusions, including hemorrhagic effusions, and pleural fluid cytology can often reveal the malignant cells

Mesothelioma of the lung

Mesothelioma of the Lung – Gross

The dense white encircling tumor mass is arising from the visceral pleura and is a mesothelioma. These are big bulky tumors that can fill the chest cavity. The risk factor for mesothelioma is asbestos exposure.

Mesothelioma of the Lung – Gross

RESPIRATORY: Pleura: Mesothelioma: Gross natural color external view of lung with nodules of tumor on pleura

Mesothelioma of the Lung – MPF

Mesotheliomas have either spindle cells or plump rounded cells forming gland-like configurations, as seen here at high power microscopically. They are very difficult to diagnose cytologically.

Mesothelioma of the Lung – HPF

Mesothelioma: Micro epithelial pattern spindle cells or plump rounded cells forming gland-like configurations

GOOD *LUCK*
