

DIFFERENT CLASSES OF ANTIBIOTICS - AN OVERVIEW

Key: ● COMMONLY ACT AS BACTERIOSTATIC AGENTS, RESTRICTING GROWTH & REPRODUCTION ● COMMONLY ACT AS BACTERICIDAL AGENTS, CAUSING BACTERIAL CELL DEATH

Bactericidal

- rifampicin
- vancomycin
- fluoroquinolones
- penicillins
- aminoglycosides
- polymyxins
- * macrolides
- bacitracin
- cephalosporins
- metronidazole

really very finely proficient at predicting many bacterial cell murders

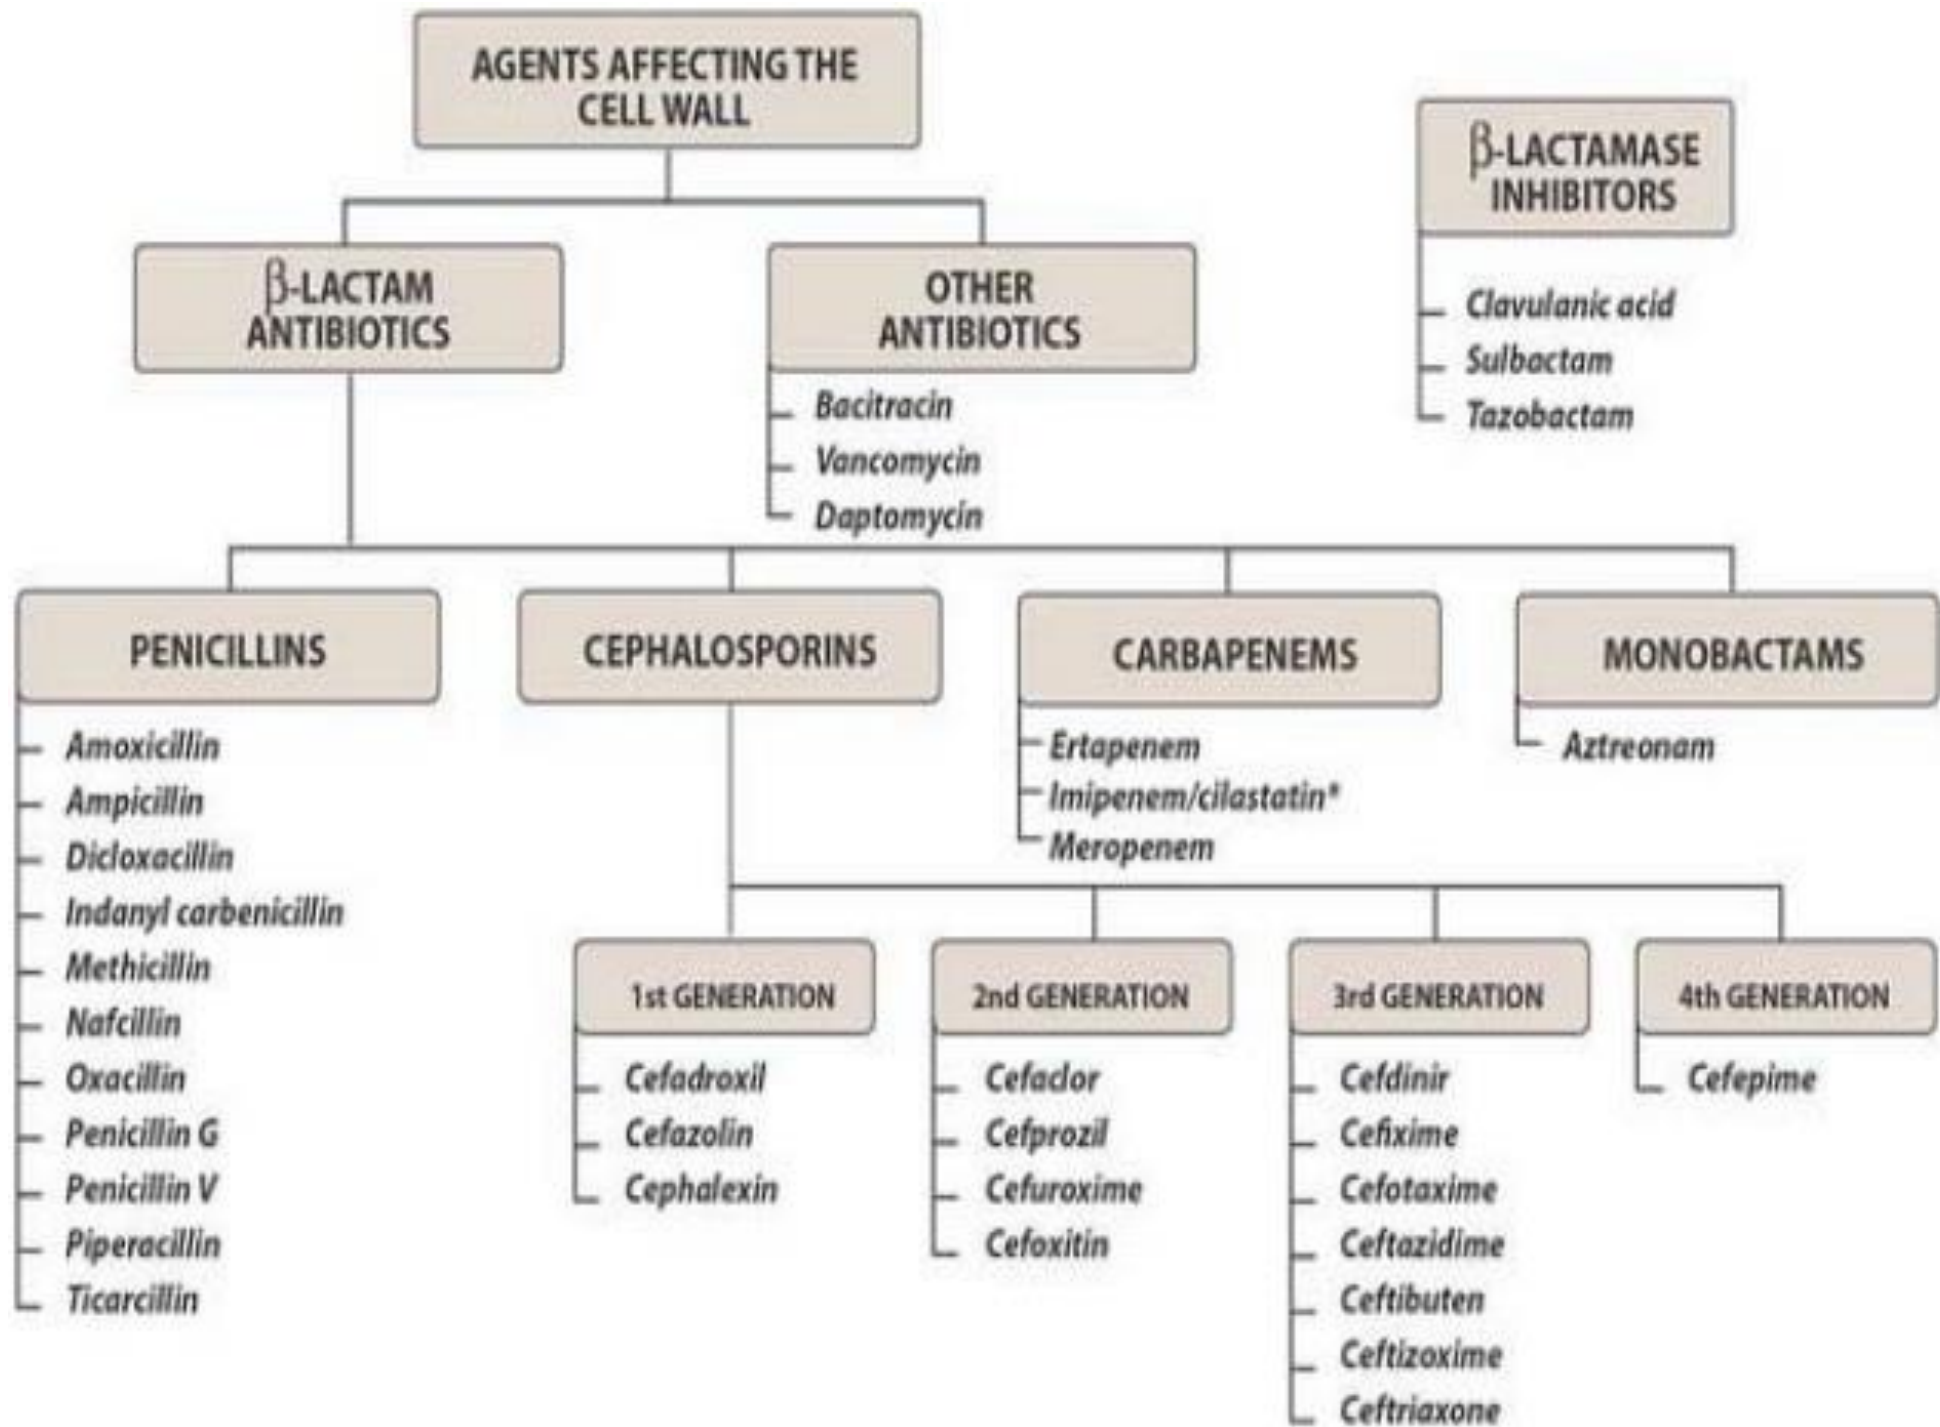

Bacteriostatic

- erythromycin (macrolides)
- chloramphenicol
- sulfonamides
- tetracycline
- trimethoprim
- clindamycin

ECStATIC about bacteriostatic:

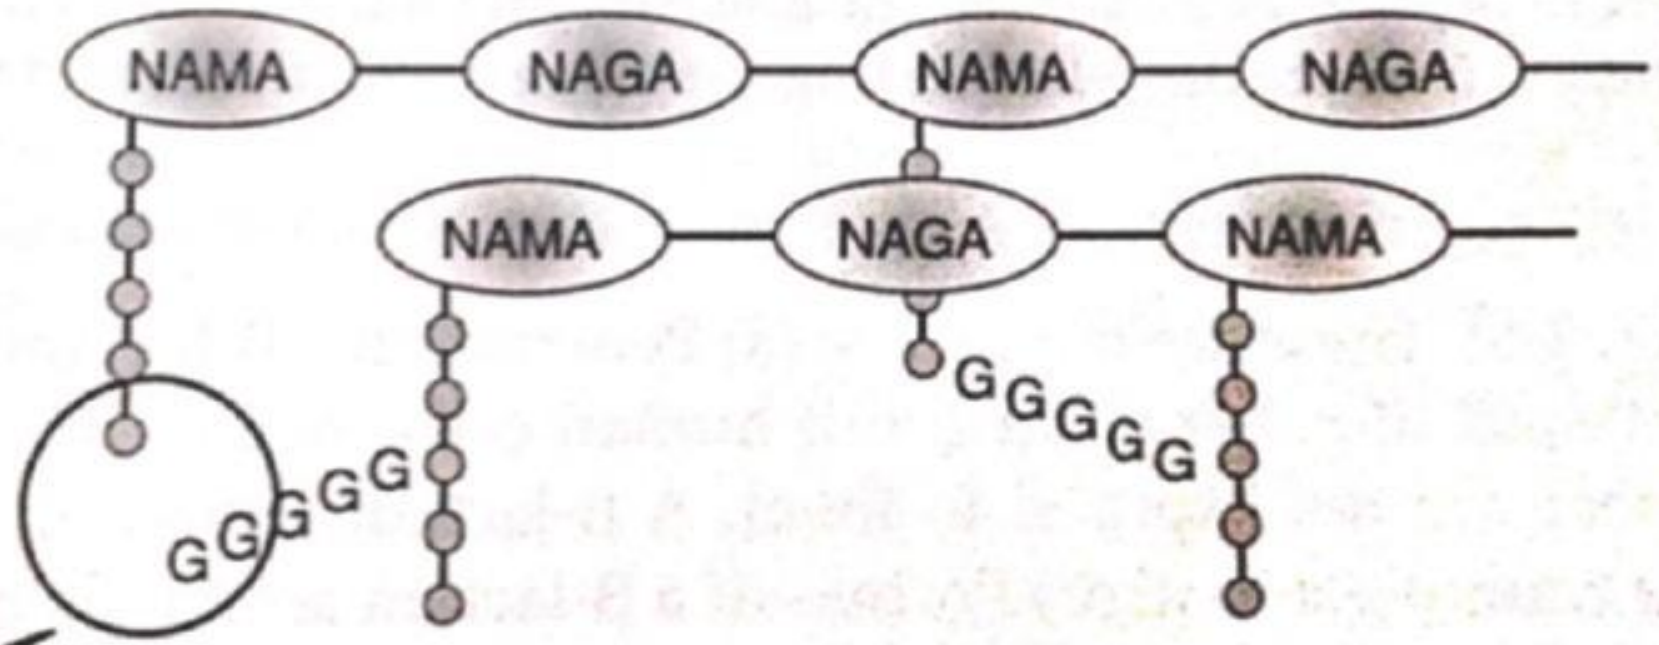

Combination Therapy

- synergy: penicillin (cell wall) and aminoglycoside (protein synthesis) -> drug can get into cell to target ribosome
- antagonism: don't combine bactericidal with bacteriostatic drug -> instead, use two cidal or two static!

Protein biosynthesis

Cell Wall Synthesis

Beta Lactams

Penicillins
Cephalosporins
Carbapenems
Monobactams

Vancomycin

Bacitracin

Cell Membrane

Polymyxins

Folate synthesis

Sulfonamides
Trimethoprim

PABA
DHF A
THF A

Nucleic Acid Synthesis

DNA Gyrase

Quinolones

RNA Polymerase

Rifampin

50S

30S

50S subunit

Macrolides
Clindamycin
Linezolid
Chloramphenicol
Streptogramins

30S subunit

Tetracyclines
Aminoglycosides

Protein Synthesis

Gram Positive

Plasma Membrane

Periplasmic space

Peptidoglycan

Plasma Membrane

Periplasmic space

Peptidoglycan

Outer membrane
(lipopolysaccharide
and protein)

Gram Negative
