## Molecular biology (2)

(Foundation Block)

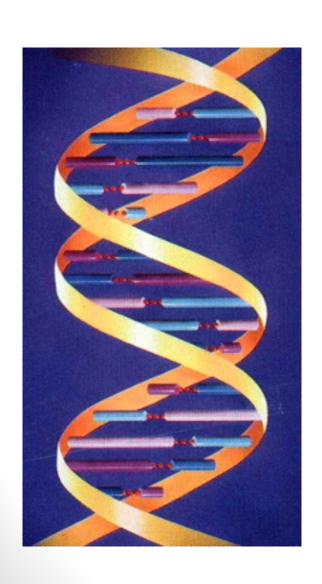

Dr. Essa Sabi

### **Objectives**

By the end of this lecture, the students should be able to:

- To understand DNA replication
- To know the transcription of genetic material into messenger RNA
- To get an idea about the translation of mRNA into a functional protein.

### DNA is the genetic material

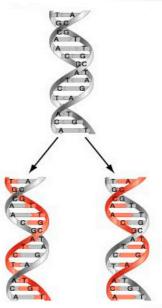

#### Therefore it must:

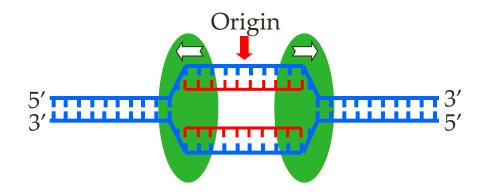

- 1. Replicate faithfully.
- 2. Have the coding ability to produce proteins for all cellular functions.

### Features of Eukaryotic DNA Replication

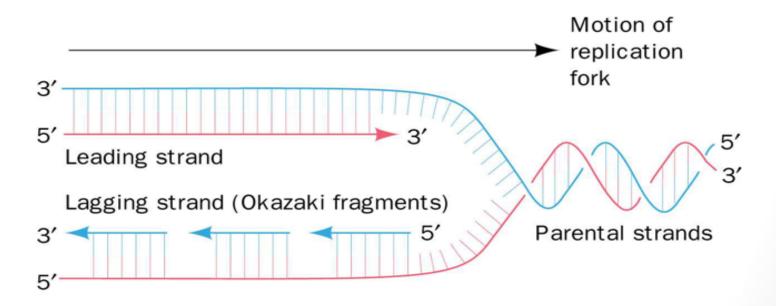

- 1 Semiconservative with respect to parental strand:
  - Daughter DNA molecules contain one parental strand and one newly-replicated strand.

2 Bidirectional with multiple origins of replication.

- 3 Primed by short stretches of RNA.
- 4 Semi-discontinous

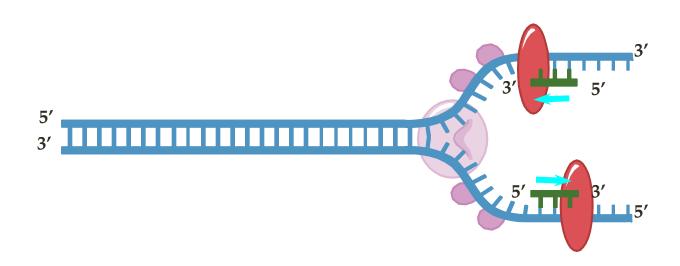

Semidiscontinuous DNA replication. In DNA replication, both daughter strands (*leading strand red*, *lagging strand blue*) are synthesized in their  $5' \rightarrow 3'$  directions

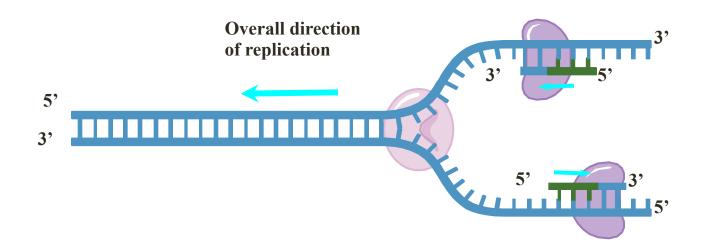

# Proteins involved in DNA Replication

- 1 DNA Helicase.
- 2 Single-stranded DNA binding proteins.
- (3) DNA Primase.
- 4 DNA polymerases (5 types:  $\alpha$ ;  $\beta$ ;  $\gamma$ ;  $\delta$ ;  $\epsilon$ ).
- 5 DNA ligase.
- 6 Topoisomerases:
  - 1 Topoisomerase I.
  - 2 Topoisomerase II.
- 7 Telomerases

### Steps in DNA Replication

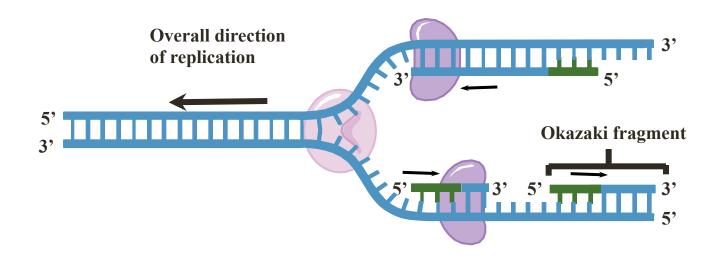

- Helicase protein binds to DNA sequences called origins and unwinds DNA strands.
- Single-Stranded binding proteins prevent single strands from rewinding.
- Primase protein makes a short segment of RNA primer complementary to the DNA.

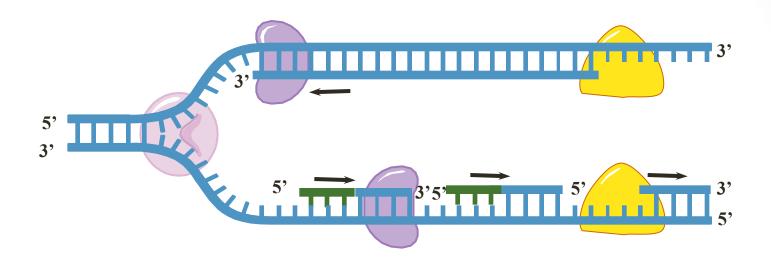

#### **DNA** polymerase:

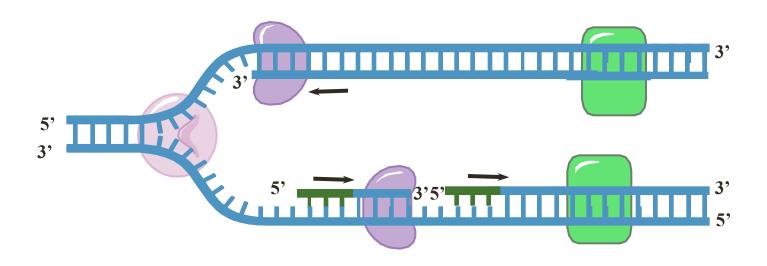

- > Adds DNA nucleotides to the RNA primer.
- > Proofreads bases added and replaces incorrect nucleotides

- Leading strand synthesis continues in a 5' to 3' direction.
- Discontinuous synthesis produces 5' to 3' DNA segments (Okazaki fragments).

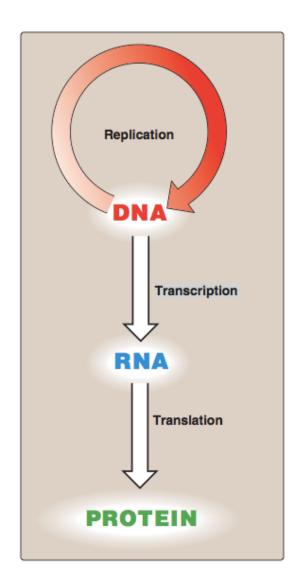

Exonuclease activity of DNA polymerase removes RNA primers

- DNA polymerase fills the gaps.
- Ligase forms bonds between sugar-phosphate backbone

### The central dogma of Molecular Biology

A portion of **DNA**, called a **gene**, is transcribed into **RNA**.

RNA is translated into **proteins**.

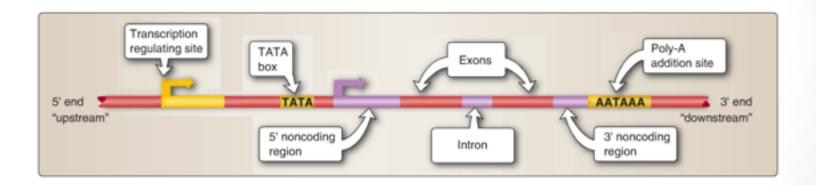

### Transcription (mRNA synthesis)

- A portion of DNA (a gene) is transcribed into messenger RNA (mRNA).
- Only one of the DNA strands is transcribed (antisense strand).
- The RNA polymerase II is responsible for this process.
- The direction of transcription is  $5' \rightarrow 3'$ .

### Steps of mRNA synthesis

#### Chain initiation:

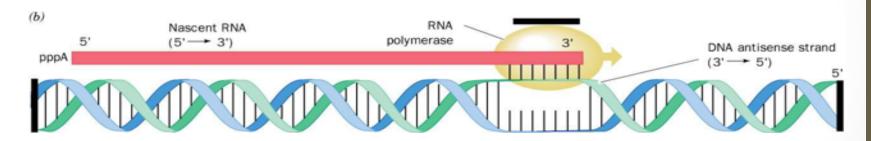

• RNA polymerase II binds to *promoter region* of DNA to start transcription.

### Steps of mRNA synthesis

#### Chain elongation:

- A portion of DNA template unwinds (opens) at the point of RNA synthesis.
- This forms a short length of RNA-DNA hybrid.

#### Chain termination:

• DNA contains specific sites which stop transcription (at a sequence of 4-10 AT base pairs).

### Post-transcriptional modification

• **Capping:** Addition of a methylated guanine nucleotide at 5' end of mRNA

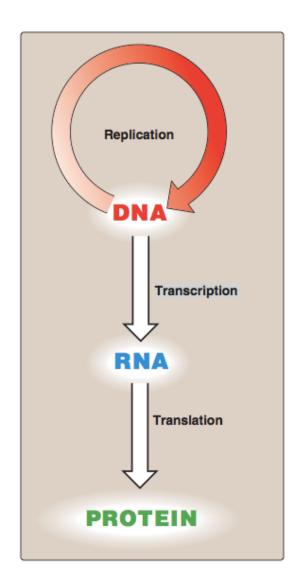

#### Function:

- To prevent mRNA degradation by exonucleases.
- It helps the transcript bind to the ribosome during protein synthesis.
- **Polyadenylation:** Addition of a poly(A) tail (a highly conserved AAUAA sequence) at 3' end of mRNA.

#### *Functions*:

- *To protect the mRNA from degradation*
- For ribosomal RNA recognition
- Intron removal for releasing mature mRNA from nucleus.

### The central dogma of Molecular Biology

A portion of **DNA**, called a **gene**, is transcribed into **RNA**.

RNA is translated into **proteins**.

### Translation (Protein synthesis)

- A process of protein synthesis from mRNA
- mRNA has genetic codes for amino acids present in proteins.
- The **genetic code** is a dictionary that identifies the correspondence between a sequence of nucleotide bases and a sequence of amino acids.
- Each individual word in the code is composed of three nucleotide bases (**codons**).

#### 64 possible codons:

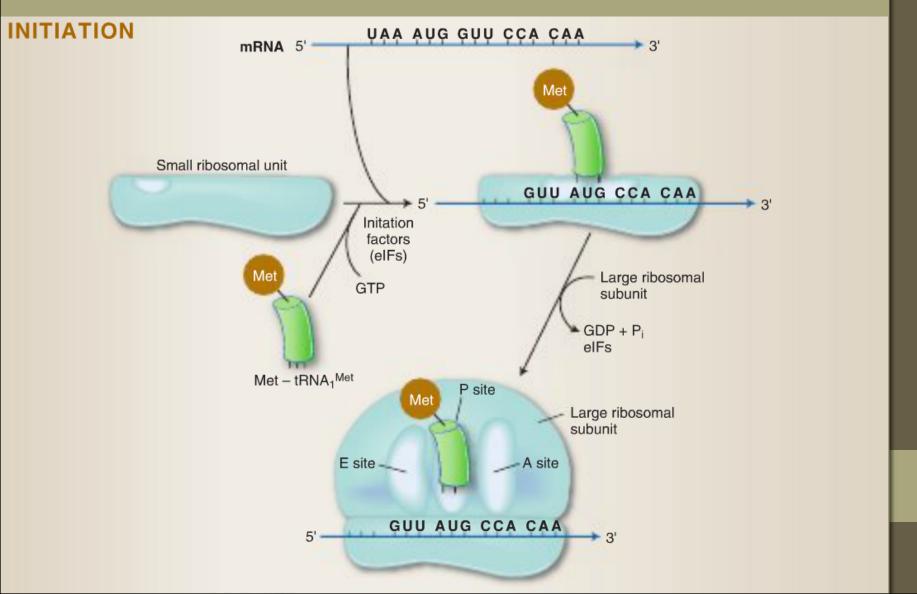

- 61 codons specify 20 amino acids
- One start codon (AUG)
- 3 stop codons
  UAA, UAG and UGA

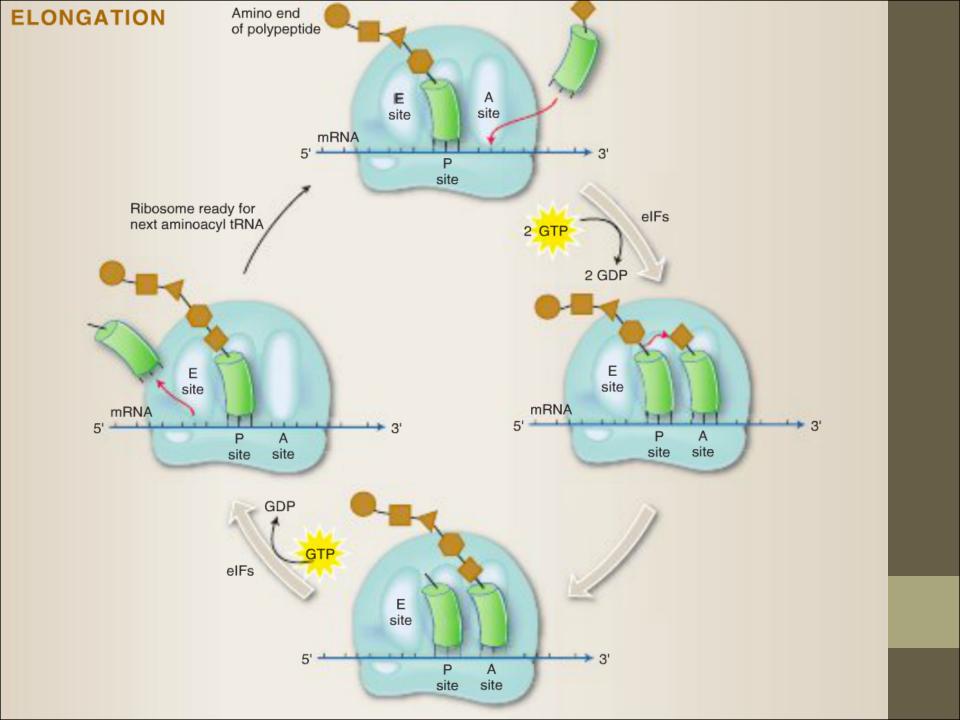

First position (5' end)	Second position				Third position (3' end)
	U	C	A	G	
U	UUU Phe	UCU	UAU Tyr	UGU Cys	U
	UUC	UCC Ser	UAC	UGC	$\mathbf{C}$
	UUA Leu	UCA	UAA Stop	UGA Stop	$\mathbf{A}$
	UUG	UCG	UAG Stop	UGG Trp	G
C	CUU	CCU	CAU	CGU	U
	CUC	CCC Pro	CAC His	CGC	C
	CUA Leu	CCA	CAA	CGA Arg	$\mathbf{A}$
	CUG	CCG	CAG Gln	CGG	$\mathbf{G}$
A	AUU	ACU	AAU	AGU Ser	U
	AUC Ile	ACC Thr	AAC Asn	AGC Ser	C
	AUA	ACA THI	AAA	AGA	$\mathbf{A}$
	AUG Met <sup>b</sup>	ACG	AAG Lys	AGG Arg	G
G	GUU	GCU	GAU A	GGU	U
	GUC Val	GCC	GAC Asp	GGC	C
	GUA Val	GCA Ala	GAA	GGA Gly	$\mathbf{A}$
	GUG	GCG	GAG Glu	GGG	$\mathbf{G}$

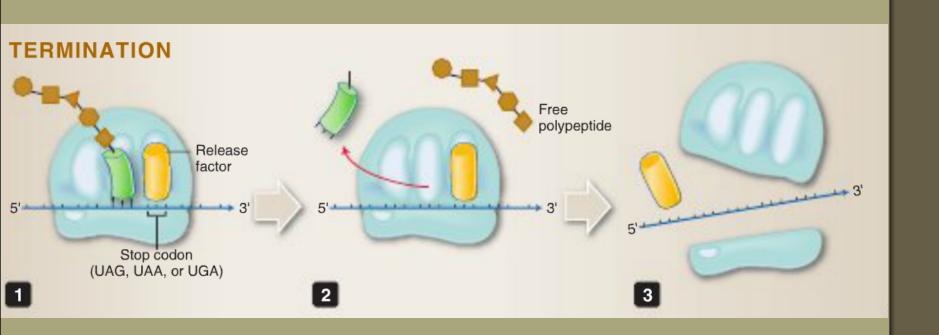

## Components required for Translation

- 1 Amino acids.
- 2 Transfer RNA (tRNA).
- 3 Aminoacyl-tRNA synthetases.
- (4) mRNA.
- 5 Functionally competent ribosomes.
- 6 Protein factors.
- (7) ATP and GTP.

### Steps in Protein Translation

### Take home messages

- DNA is the genetic material, so it must replicate faithfully and have the coding ability to produce proteins for all cellular functions.
- Only one strand of DNA (antisense strand) is transcribed into mRNA.
- The synthesized mRNA is protected from the destruction and prepared for translation through post-transcriptional modification.
- mRNA transcription and protein synthesis processes are the same in both prokaryotic eukaryotic cells with some differences.
