

## Drug for Parkinson's disease

Drug	Uses	Pharmacokinetics	Side effect	Drug interaction	Contraindication
<b>Levodopa (L-dopa)</b>	<p>1-Precursor of dopamine</p> <p>2-<b>First line treatment</b></p> <p>3-used combined with <b>carbidopa</b> (Peripheral dopa decarboxylase inhibitor):</p> <p>*To inhibit peripheral conversion of L-dopa to dopamine</p> <p>*To decrease metabolism of L-dopa in GIT and peripheral tissues, Thus,increasing <math>t_{1/2}</math>.</p> <p>*To increase availability of levodopa.</p> <p>*To reduce dose of levodopa and side effects.</p> <p>*Do not cross BBB.</p> <p>-Note: L-Dopa Ameliorates the signs of Parkinsonism particularly bradykinesia <b>But does not cure the disease.</b></p>	<p>1-absorbed from the small intestine by active transport.</p> <p>2-Ingestion of meal especially high protein meal interferes with absorption and transport into CNS (<b>taken on empty stomach</b>).</p> <p>3- Short duration of action <math>t_{1/2}</math>= 1-2 h (<b>fluctuation of plasma concentration</b>).</p>	<p>1-On-off phenomenon (Off= akinesia or hypomobility) phenomenon (Rx MAOI-B &amp; low protein diet).</p> <p>2-Wearing-off effect (duration of "on" states becomes shorter).</p> <p>3-Dyskinesia (involuntary movements occurs in 40 to 90% of patients) <b>due to fluctuating plasma levels of levodopa and the presence of hypersensitive dopamine receptors.</b></p> <p>4-Peripheral effects:</p> <p>*Anorexia, nausea, and vomiting (<b>due to stimulation of emetic center</b>).</p> <p>*Mydriasis, orthostatic hypotension, cardiac arrhythmias.</p> <p>5-CNS effects: (<b>Psychological disorders</b>) mainly psychosis, delusions, hallucinations, confusion, sleep disturbances and depression.</p>	<p>1-Proteins ingested with meals.</p> <p>2-<b>Pyridoxine (Vitamin B6)</b> bez it diminished the effect of the drug due to increased peripheral metabolism.</p> <p>3-<b>Nonselective MAO inhibitors</b> (phenelzine) it will cause <b>hypertensive crisis</b> due to increased catecholamines (NE).</p>	<p>1-Psychotic patient.</p> <p>2-Closed angle glaucoma (<b>due to mydriatic effect</b>).</p> <p>3-Patients with history of melanoma <b>Why?</b> Bez <b>L-dopa is a precursor of melanin.</b></p>

<b>Amantadine</b>	<p>1-originally introduced as an antiviral.</p> <p>2- Amantadine increases dopamine release.</p> <p>3-Acts as an antagonist at muscarinic and NMDA (<i>N-methyl-D-aspartate</i>) receptors.</p> <p>4- modestly effective in treating symptoms of parkinsonism but last only for short period (few weeks) and only used for L-Dopa resistance.</p>	<p>1-given orally with short half life.</p> <p>2-most of the drug being excreted unchanged in the urine.</p>	<p>1-Nausea, anxiety, insomnia, confusion, hallucinations (dopamine like side effects).</p> <p>2-Dry mouth, urinary retention (anticholinergic effects).</p> <p>3-Restlessness and hallucinations (NMDA antagonist).</p>		
<b>Dopamine receptor agonists</b>	<p>➤ <u>Ergot derivatives</u> Bromocriptine</p> <p>➤ <u>Non ergot derivatives</u> Pramipexole</p> <p>1-Dopamine agonists are used in advanced Parkinson's disease with fluctuation and dyskinesia.</p> <p><u>Bromocriptine</u></p> <p>1-Bromocriptine, an ergot derivative, is an agonist at D2-receptors.</p> <p>2-Rx of hyperprolactinemia (<i>galactorrhea</i>)</p> <p>3-Rx of infertility in women.</p> <p><u>Pramipexole</u></p> <p>1-Non Ergot dopamine agonist</p> <p>2-Used alone or in combination with L-Dopa.</p> <p>3-Has the advantage of being free radicals scavenger.</p>	<p>1-Have longer duration of action than L-dopa (<i>less likely to cause dyskinesias than levodopa</i>)</p> <p><u>Bromocriptine</u></p> <p>1-Is given orally, short t<sub>1/2</sub>.</p>	<p><u>Bromocriptine</u></p> <p>1-Nausea, vomiting, postural hypotension</p> <p>2-Confusion, hallucinations, delusions</p> <p>3-Dyskinesias (<i>less prominent</i>).</p> <p>4-To minimize adverse effects, the dose is built up slowly over 2 or 3 months.</p> <p><u>Pramipexole</u></p> <p>1-similar to L-Dopa, but less dyskinesias.</p>		<p><u>Bromocriptine</u></p> <p>1-Psychosis</p> <p>2-Peripheral vascular disease</p> <p>3-Recent myocardial infarction</p>

<b>Selegiline</b>	<p>1-Selegiline is an irreversible inhibitor of <b>MAO-B</b>.</p> <p>2-It inhibits dopamine degradation by MAO-B in CNS.</p> <p>3-It increases dopamine available for its receptors.</p> <p>4-It slows the disease progression by reducing the formation of toxic <i>free radicals</i> produced during dopamine metabolism (<b>antioxidant</b>).</p> <p>5-Selegiline is metabolized to desmethylselegiline, <i>Which is (antiapoptotic)</i>.</p> <p>6-As monotherapy, may be effective in the <b>newly diagnosed patient with parkinsonism</b>.</p> <p>7- Combined with levodopa / carbidopa in <b>later-stage parkinsonism</b> to:</p> <ul style="list-style-type: none"> <li>*reduce the required dose of levodopa</li> <li>*delay the onset of dyskinesias and motor fluctuations that usually accompany long-term treatment with levodopa.</li> </ul>		<p>1-At high doses, selegiline may inhibit MAO-A (<i>hypertensive crises</i>).</p> <p>2-May cause insomnia when taken later during the day</p>		<p>1-Selegiline should not be co-administered with tricyclic antidepressants, or selective serotonin reuptake inhibitors (<i>may cause hyperpyrexia, agitation, delirium, coma</i>).</p>
-------------------	---	--	--	--	--

<b>COMT Inhibitors (Catechol-O-methyl transferase) Inhibitors</b>  <b>Entacapone</b>	<p>1-Acts peripherally and centrally to inhibit COMT enzyme required for dopamine degradation.</p> <p>2-It is used: as adjuvant to L-Dopa to:</p> <ul style="list-style-type: none"> <li>– Decrease fluctuations</li> <li>– Improve response</li> <li>– Prolonged the ON-Time.</li> </ul>		<p>1-L-Dopa side effects.</p> <p>2-Orange discoloration of urine.</p>		
<b>Anticholinergic Drugs</b> <b>Benztropine</b>	<p>1-muscarinic antagonist.</p> <p>1-Has modest anti- parkinsonian actions.</p> <p>3-used during the early stages of the disease or as an adjunct to levodopa therapy.</p> <p>4-Provide benefit in drug-induced parkinsonism (antipsychotics).</p>		<p>1-Cycloplegia, dry mouth, urinary retention, and constipation.</p> <p>2-Confusion, delirium, and hallucinations may occur at higher doses.</p>		<p>1-Prostatic hypertrophy</p> <p>2-Glaucoma</p> <p>3-Intestinal obstruction</p>
