

# Gastrointestinal Physiology (Lecture 7)

Physiology of The Colon: Motility

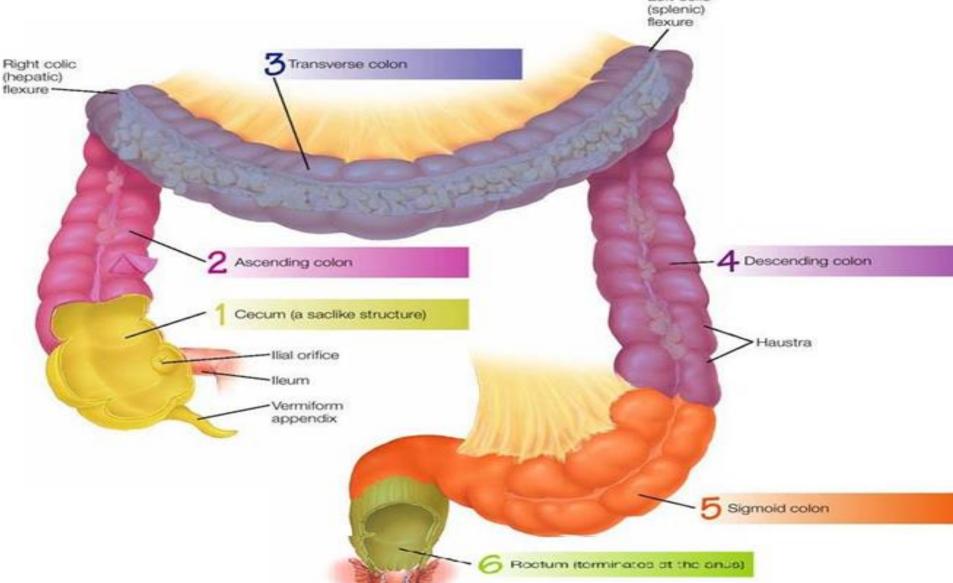

Dr. Hayam Gad

### Learning Objectives

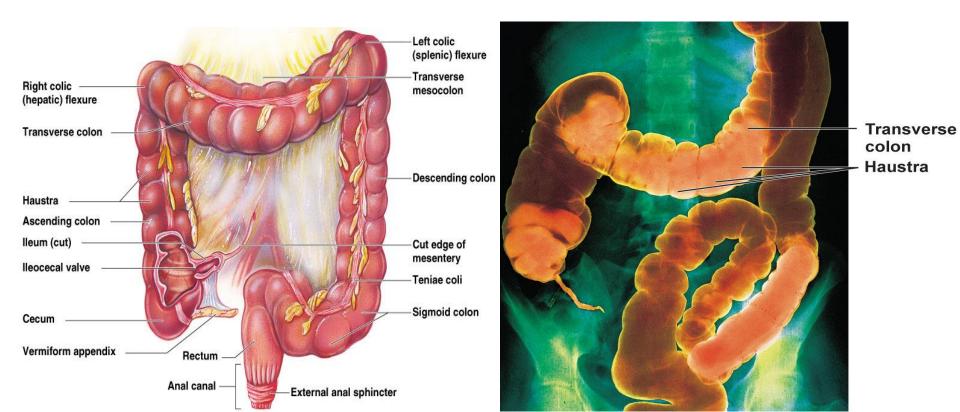

- \*Parts of the Colon
- \*Functions of the Colon
- \*The physiology of Different Colon Regions
- \*Secretion in the Colon
- \*Absorption in the Colon
- \*Bacterial Action in the Colon
- \*Motility in the Colon
- **☼** Defecation Reflex

## Parts of The Colon (splenic)

### The Colon

- The outer longitudinal muscle layer is modified to form three longitudinal bands called **tenia coli** visible on the outer surface.
- Since the muscle bands are shorter than the length of the colon, the colonic wall is sacculated and forms **haustra**.

- The mucous membrane of the colon lacks villi and has many crypts of Lieberkühn.
- They consist of simple short glands lined by mucous-secreting goblet cells.
- The epithelial cells contain almost no enzymes.
- The colon has a length of 150 cm.
- The transit of small labeled markers through the large intestine occurs in 36-48 hrs.

### Functions of The Colon

- ✓ Absorb vitamins produced by bacteria
- ✓ Reabsorb water and compact material into feces
- ✓ Store fecal matter prior to defecation

## The Physiology of Different Colon Regions

#### 1. The ascending colon:

Specialized for processing chyme delivered from the terminal ileum.

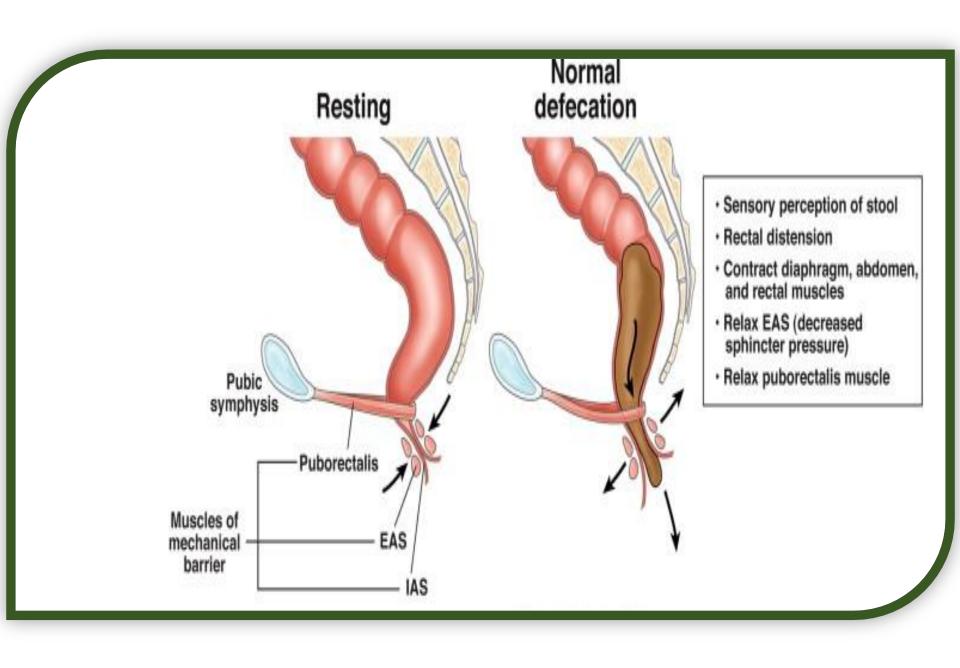

#### 2. The transverse colon:

Specialized for the storage and removal of water & electrolytes from feces.

#### 3. The descending colon:

A conduit between the transverse and sigmoid colon. This region has the neural program for power propulsion that is involved in **defecation reflex**.

- 4-The rectosigmoid region, anal canal, together with pelvic floor musculature maintains fecal continence.
  - The sigmoid and rectum are reservoirs with a capacity of up to 500 mL.
  - The puborectalis muscle and external anal sphincter comprise a functional unit that maintain continence.
  - Fibers of puborectalis pass around the anorectum and join behind it to form a U-shaped sling (physiological valve).

### Secretion in The colon

It is mainly mucus, no digestive enzymes.

The mucus has the following functions:

- 1- It neutralizes against any acids present.
- 2- It protects against irritation.
- 3- It helps to lubricate feces.
- 4- It provides a binding medium for fecal matter.

- ☆Stimulation of the pelvic nerves cause:
  - •Marked increase in mucus secretion.
  - •Increase in peristaltic motility of the colon.

☆ During extreme parasympathetic stimulation, so much mucus can be secreted into the large intestine that the person has a bowel movement of ropy mucus as often as every 30 minutes; this mucus often contains little or no fecal material.

### Secretion of Water and Electrolytes

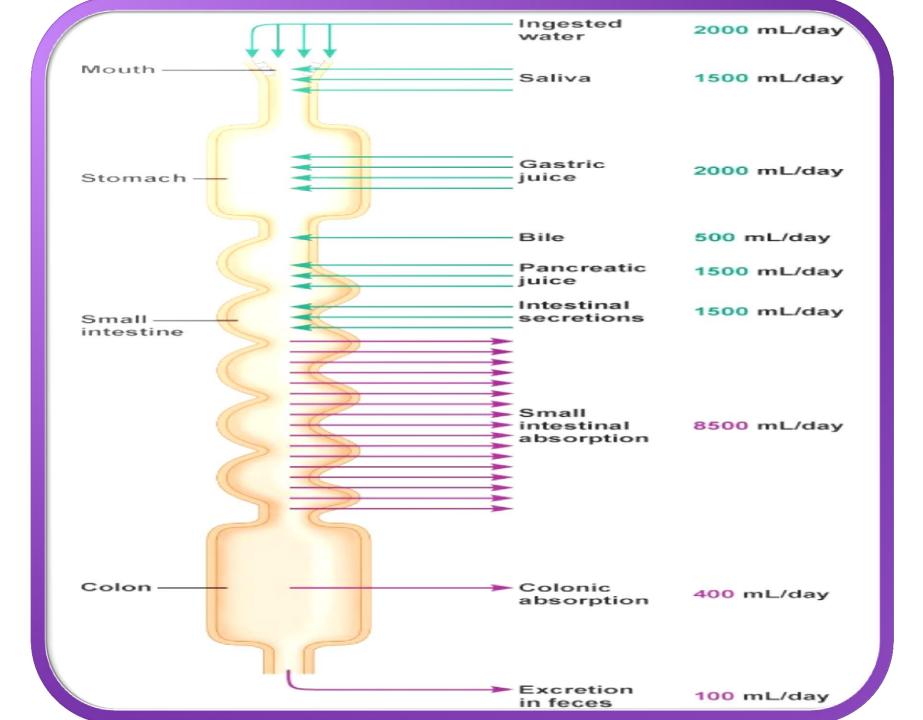

- ♦ Whenever a segment of large intestine becomes irritated as occurs in bacterial infection, the mucosa secretes large amount of water & electrolytes in addition to the alkaline mucus.
- ♦ This dilute the irritating factors and causes rapid movement of the feces toward the anus.

### Absorption in The Colon

Most of absorption in the colon occurs in the proximal half of the colon (absorptive colon). Whereas the distal colon function for storage (storage colon).

• Water absorption, about 0.5- 1.5L/day is absorbed. The net water loss is 150-200 ml/day.

N.B: The large intestine can absorb a maximum of 5 to 8 liters of fluid and electrolytes each day.

- 2 Na<sup>+</sup> is actively absorbed (in the presence of Na<sup>+</sup>-K<sup>+</sup> ATPase) at the basolateral membrane.
- **3** K<sup>+</sup> is secreted into the lumen of colon.
- Cl<sup>-</sup> is absorbed in exchange for HCO<sub>3</sub><sup>-</sup> which is secreted.
- Vitamins as Vit. K, biotin, B<sub>5</sub>, folic acid and some AA and short chain FA resulting from bacterial fermentation of CHO are absorbed.
- **6** Certain drugs as steroids and aspirin may be absorbed.
- ₱ Bile salts and organic wastes as urobilinogens and sterobilinogens can be absorbed.

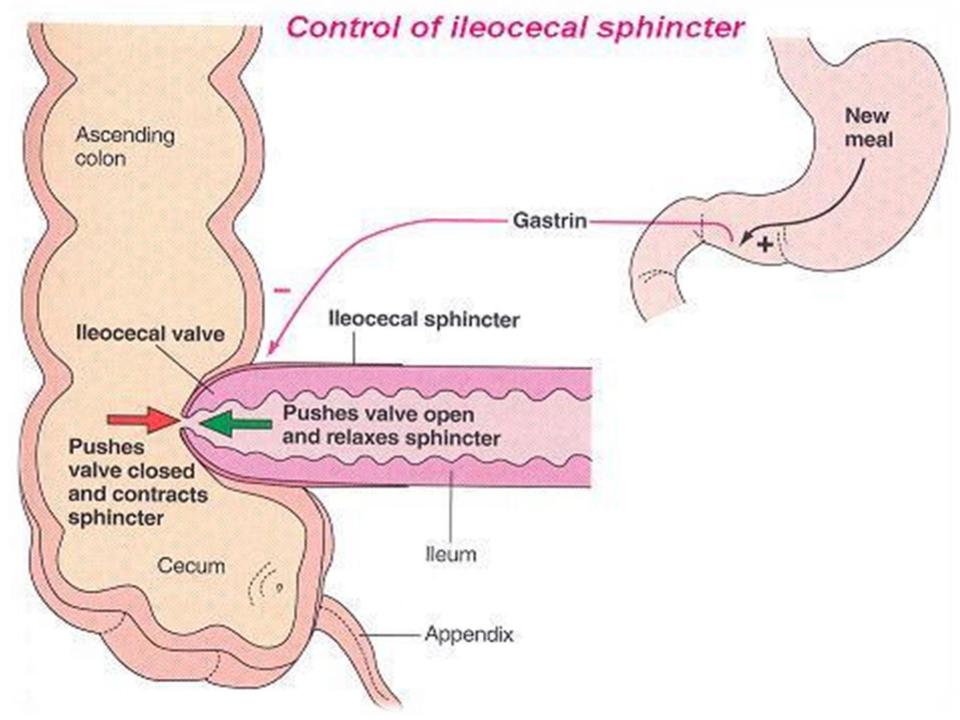

#### **Bacterial Action in The Colon**

- This bacterial flora is living in symbiosis with human and its effects are beneficial to the body as follows:
  - $\bigcirc$ Synthesis of vitamin K and some B group vitamins as folic acid, biotin, thiamine and B<sub>12</sub>.
    - The bacteria-formed vitamin K is especially important because the amount of this vitamin in the daily ingested foods is normally insufficient to maintain adequate blood coagulation.
  - Deconjugation and decarboxylation of Bile salts.

- 3 Break down of bile pigments to produce stercobilinogen.
- Decarboxylation of some AA to produce amine and histamine. The amines are excreted in feces and are responsible for its smell.
- ⑤Break down of urea by bacterial urease to ammonia. Most ammonia is absorbed and reconverted into urea by liver. In hepatic failure, accumulation of ammonia can cause hepatic encephalopathy.
- ©Fermentation of undigested CHO.

#### The Ileocaecal Valve

- ☆It prevents backflow of contents from colon into small intestine.
- ☆It remains closed and open only when an intestinal peristaltic wave reaches it.
- ☆ Distension of the cecum, Secretin, Ach, alpha adrenergic stimulation **contract** ileocaecal valve.
- ☆Gastrin, CCk, B adrenergic stimulation relax ileocaecal valve.

### Motility in The Colon

#### 1- Mixing Movement (Haustrations)

- The motor events in the cecum and ascending colon
- At constrictions points, 2.5 cm of the circular muscle contracts, at the same time the longitudinal strips contract.
- These combined contractions cause the unstimulated portion of large intestine to bulge outward into baglike sacs (haustrations).

- They also at times move slowly analward during their period of contraction.
- After another few minute new haustral contractions occur in other areas nearby.
- In this way all fecal material is gradually exposed to the surface of the large intestine & fluid is progressively absorbed.

#### 2- Propulsive (mass) Movement

- The motor events in transverse & descending colon
- These movements occur few times each day, most abundantly for 15 min during the first hour after eating breakfast.
- OA constrictive ring occurs at a distended or irritated point in the colon. Then rapidly the 20 or more cm of the colon distal to the constriction contract almost as a unit forcing the fecal material en mass down the colon.

- O It starts at the middle of transverse colon and is preceded by relaxation of the circular muscle and the downstream disappearance of haustral contractions
- The initiation of contraction is complete in about 30 seconds.
- © During the next 2 to 3 min another mass movement occurs.
- the whole series of mass movement will usually persist for only 10 min to half an hour. They will then return after a half day or even a day later.

When they have forced a mass of feces into the rectum the desire for defecation is felt.

#### > Initiation of Mass Movement:

- ♣ Gastrocolic & duodenocolic reflexes after meals. They result from distension of the stomach & duodenum.
- ♣ Irritation of the colon e.g., castor oil.
- ♣ Intense stimulation of parasympathetic NS.
- ♣ Over distension of a segment of the colon.

#### 3- Antiperistalsis

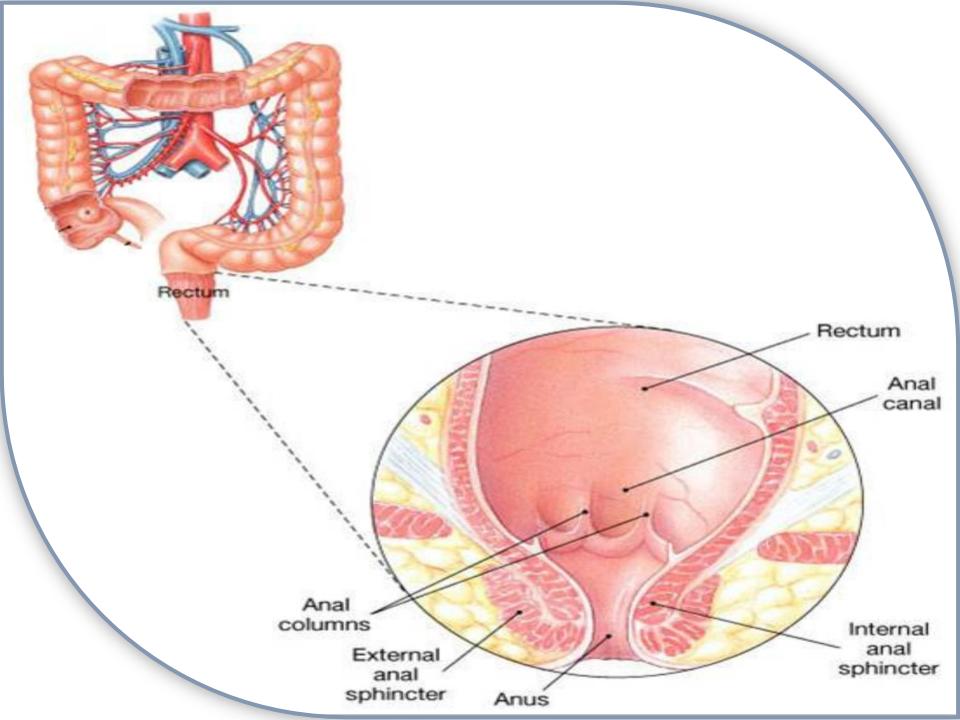

- ✓ It starts at the junction of ascending and transverse colon and traveling towards the cecum.
- ✓ It mixes contents and help water absorption.

### **Control of Colonic Motility**

- The intramural plexuses directly control the contractile behavior of the colon.
- Stimulatory enteric motor neurons use acetylcholine & substance P as neurotransmitters.
- Inhibitory enteric motor neurons release VIP & NO onto colonic smooth muscle cells.
- The extrinsic autonomic nerves to the colon modulate the control of the colonic motility by the enteric nervous system.

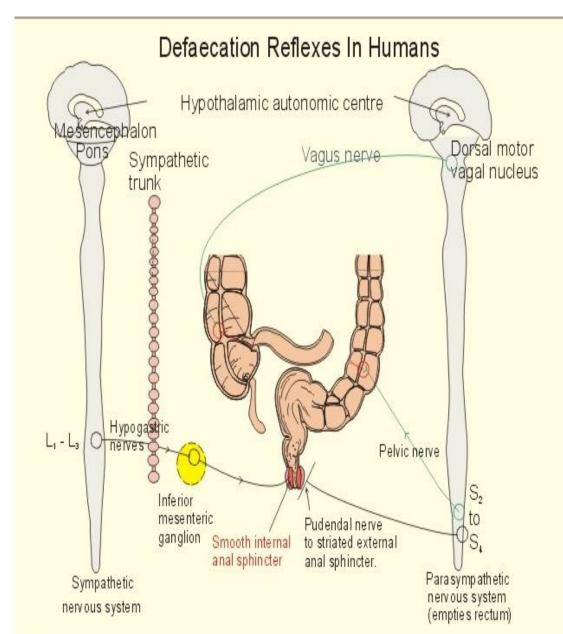

#### The Rectum

- Last portion of the digestive tract that terminates at the anal canal.
- Mechanoreceptors in the rectum detect distention and supply the ENS.
- The anal canal in the region of the skin is innervated by somatosensory nerves that transmit signals to CNS.
- Secontraction of anal sphincters and puborectalism uscle blocks the passage of feces and maintains continence.

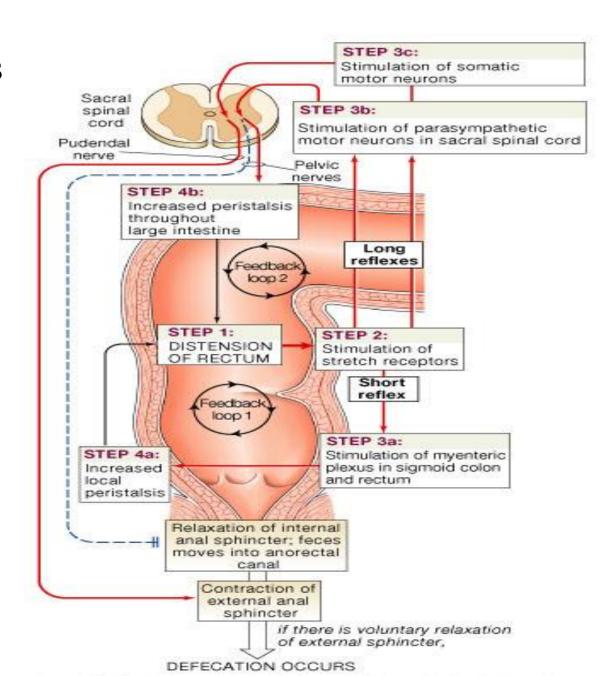

### **Defecation**

- ◆ It is a spinal reflex which is influenced by higher center.
- Most of the time the rectum is empty and both internal and external sphincters are reflexly maintained in a state of tonic contraction.

- Gastric or intestinal filling initiate a mass movement in the colon that pushes feces into rectum (gastrocolic & dudenocolic reflexes).
- The rectum is distended and sends signals to cerebral cortex producing the desire to defecate.

## If the surrounding circumstances are suitable

- Defecation reflex will be allowed. Stretch of the rectal wall is signaled to SC by pelvic nerve. Efferent pelvic impulses cause reflex contraction of the rectum and relaxation of IAS.
- This is followed by reduction in tonic impulses to EAS, so it relaxes and feces leave the rectum assisted by voluntary straining and contraction of pelvic floor muscle.

## If situation is not suitable for defecation

- The reflex is inhibited by the cerebral cortex.
- Tonic contraction of EAS is voluntary maintained which leads to accommodation of the rectum to distension and return of tonic contraction of the IAS.

### Fecal Incontinence

The spinal reflex of defecation operates without interference from higher centers.

#### Causes:

- In infants (physiological)
- Spinal cord lesion
- Weakness of IAS and EAS
- Weakness of pulborectalis
- Altered rectal or anal sensation
- Diarrheal conditions
- Diminished rectal capacity
