

Endocrine System Introduction

Dr. Hayam Gad Associate Professor of Physiology

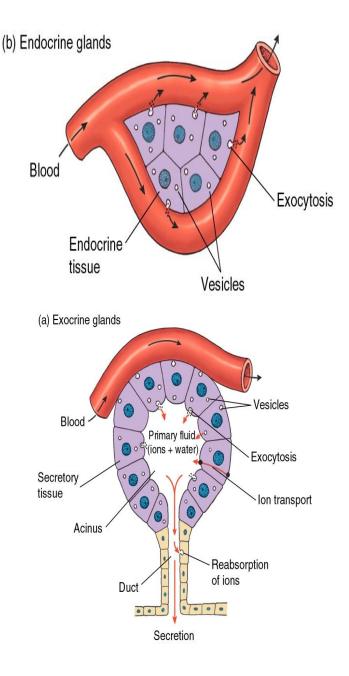

- Difference between endocrine & exocrine glands
- Chemical messengers
- Major endocrine organs
- Hormone
 - What is the hormone?
 - Types of stimuli
 - What are target cells?
 - Chemical structure
 - Transport
- Mechanism of action
 - Receptors, down-regulation & up-regulation
 - Intracellular signaling
 - Second messenger (cAMP, IP3 & tyrosine kinase)
 - Hormones interactions at target cells
 - Clearance of hormones

<u>The endocrine glands</u>

They are ductless glands that produce hormones released directly into the blood.

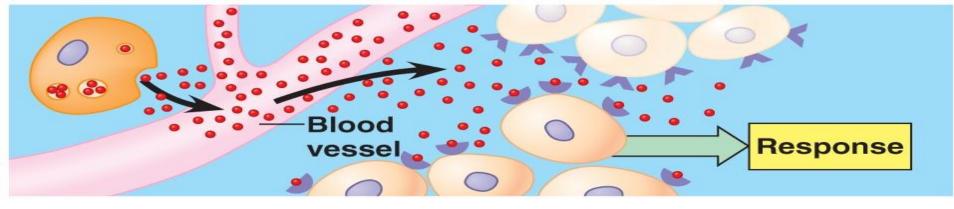

<u>The exocrine glands</u>

Release their products at the body's surface or into body cavities through ducts.

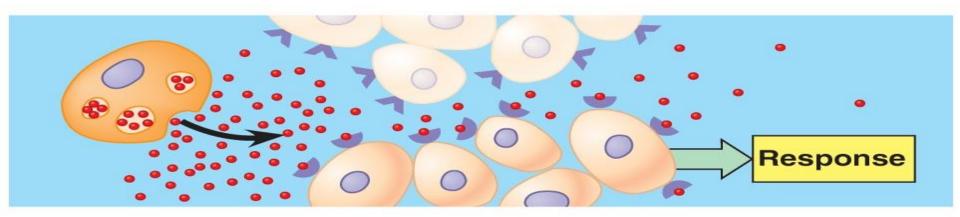

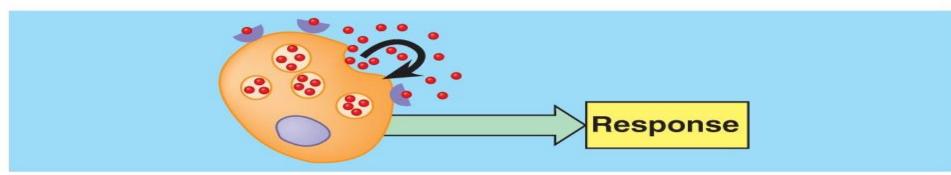

- The activities of cells, tissues and organs are coordinated by the interplay of several types of chemical messenger systems:
 - Endocrine hormones
 - Paracrines
 - Autocrines
 - Neurotransmitters
 - Neuroendocrine hormones
 - Cytokines

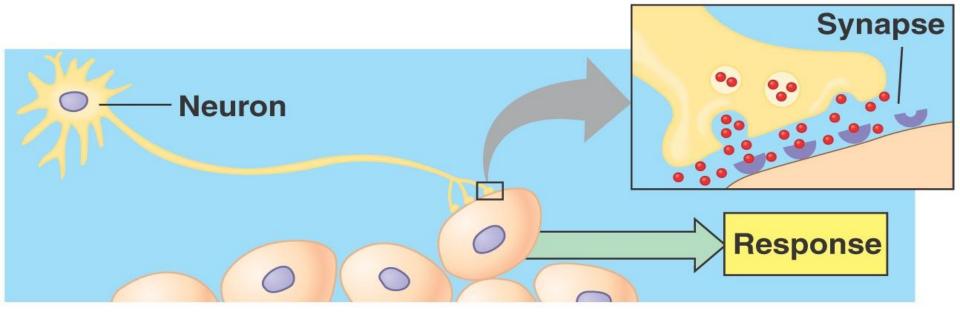

(a) Endocrine signaling: Released by glands into blood and influence the function of other cells.

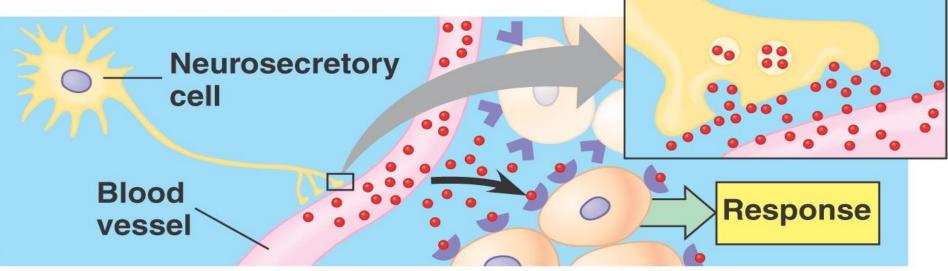

(b) Paracrine signaling :Secreted by cells into ECF and affect neighboring cells of a different type.

(c) Autocrine signaling :Secreted by cells into ECF and affect the function of the same cells.

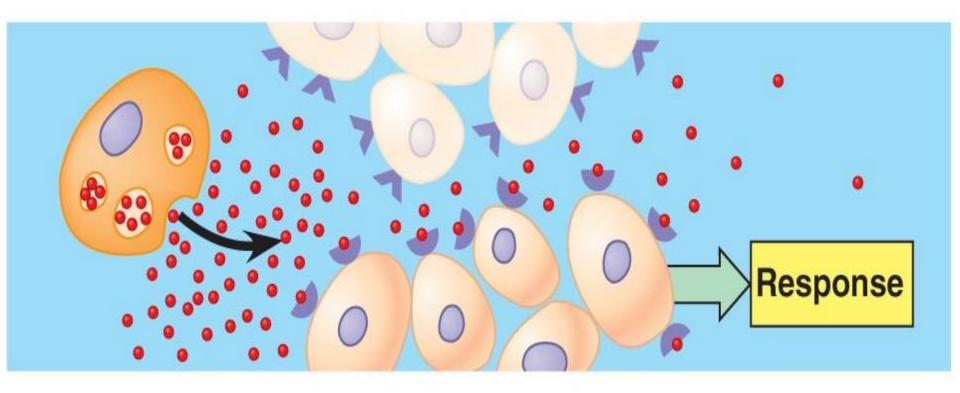

(d) Synaptic signaling (Neurotransmitters): are released by axon terminals of neurons into synaptic junctions and act locally to control nerve cell functions.

Secreted by neurons into blood and influence

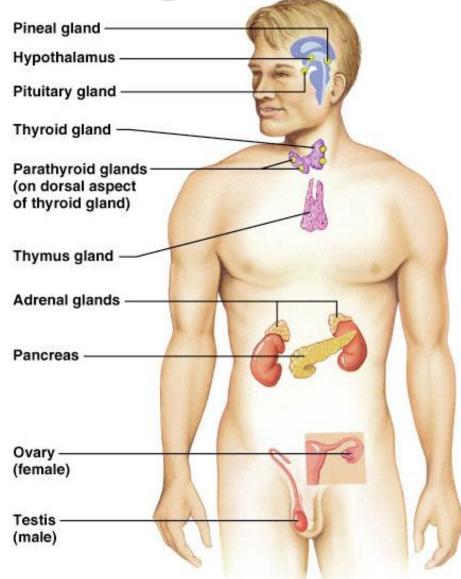

(e) Neuroendocrine signaling the function of other cells

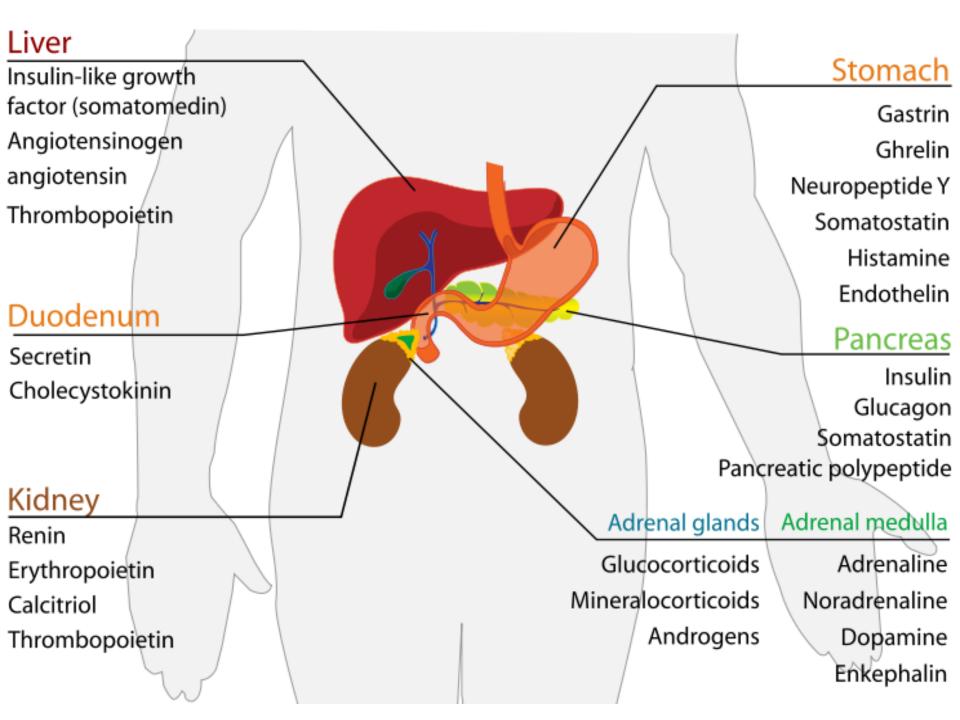

(F) Cytokines(e.g., leptin & interleukins): peptides secreted by cells into ECF and function as autocrines, paracrines, or endocrine hormones and act on other cells

Major endocrine organs

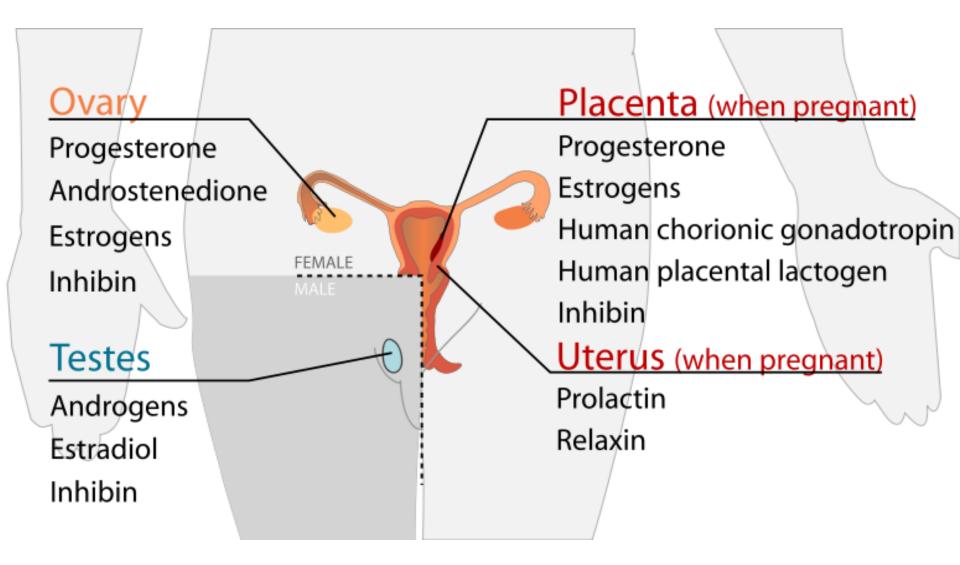

- The pituitary, thyroid, parathyroid, adrenal, the pancreas and the gonads (ovaries and testes).
- The hypothalamus, which is part of the nervous system, is also considered as a major endocrine organ.

Adipose tissue

- Leptin Estrogens
- Heart Atrial-natriuretic peptide Atrial-natriuretic peptide
- Bone Marrow Thrombopoietin

The multiple hormone systems play a key role in regulating almost all body functions:

- 1. Metabolism
- 2. Growth and development
- 3. Water and electrolyte balance
- 4. Reproduction
- 5. Behavior

What is the hormone?

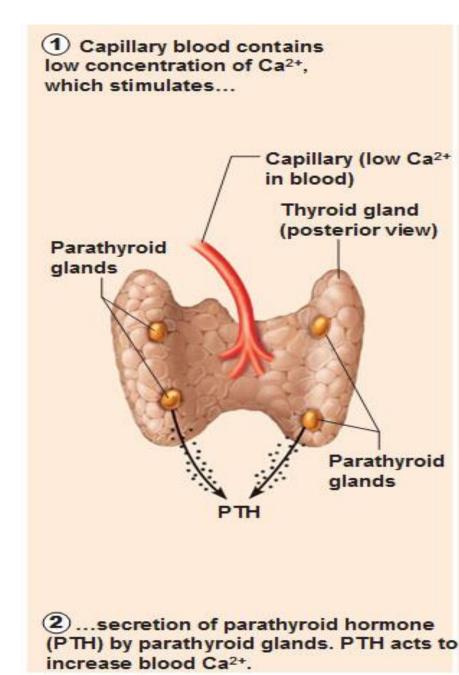

- Chemical substance secreted in a small amount from endocrine gland directly to the blood stream in response to stimulus to cause physiological responses at other type of cells (target cells).
- Hormone can affect many different types of target cells (e.g. GH and Thyroxin)
- Hormone can affect only specific target cells (e.g. ACTH and estrogen)

Classification of stimuli

- Humoral Stimuli
- Neural Stimuli
- Hormonal Stimuli

Humoral Stimuli:

Secretion of hormones in direct response to changing in blood levels of ions and nutrients

Neural Stimuli:

Nerve signals stimulate hormone release.

(b) Neural stimulus

1 Preganglionic sympathetic fibers stimulate adrenal medulla cells...

CNS (spinal cord)

Preganglionic sympathetic fibers

Medulla of adrenal gland

2...to secrete catecholamines (epinephrine and norepinephrine)

Capillary

Hormonal Stimuli:

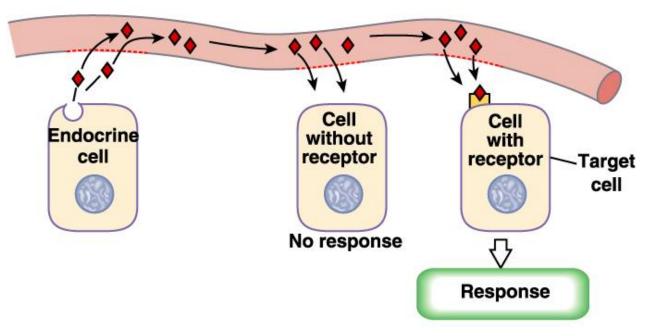

Release of hormones in response to hormones produced by other endocrine gland.

(c) Hormonal stimulus The hypothalamus secretes hormones that Hypothalamus (2) ... stimulate the anterior pituitary gland to secrete hormones Pituitary that... gland Thyroid Adrenal Gonad cortex gland (Testis) ...stimulate other endocrine glands to secrete hormones

What are target cells?

Target cells refer to cells that contain specific receptors (binding sites) for a particular hormone.

Hormone

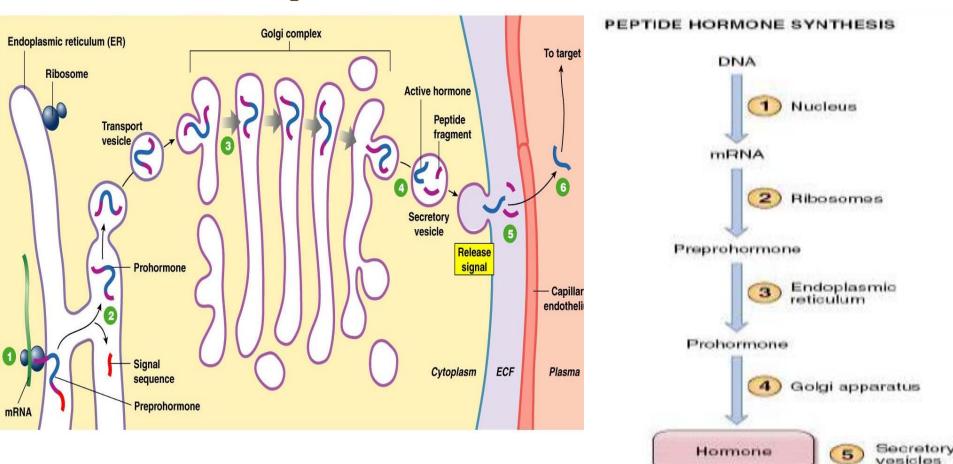

Chemical structure of hormones

Three general classes of hormones:

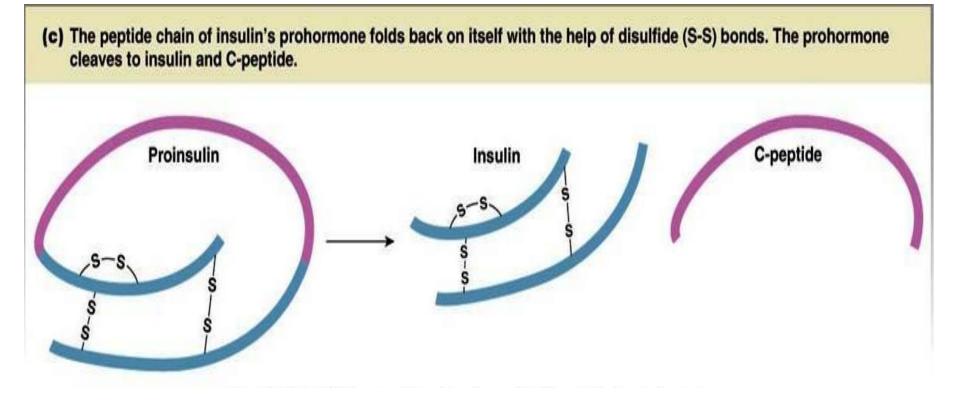

- Proteins and polypeptides (anterior and posterior pituitary, pancreatic and parathyroid hormones) stored in vesicles until needed
- Steroids (adrenocortical, ovarian and testicular hormones) diffuse across the cell membrane
- Derivatives of amino acid tyrosine (thyroid hormones and catecholamines)

Peptide (Protein) Hormones

Synthesized as preprohormone \rightarrow post-translational modification to prohormone \rightarrow then hormone

Example of protein hormone Insulin

Steroid Hormones

- •Derived from cholesterol (lipophilic)
- •Secreted by gonads, adrenal cortex, placenta
- •On-demand synthesis (SER)
- •Cross membranes (no storage)
- •Usually bound to carrier proteins

Amine Hormones

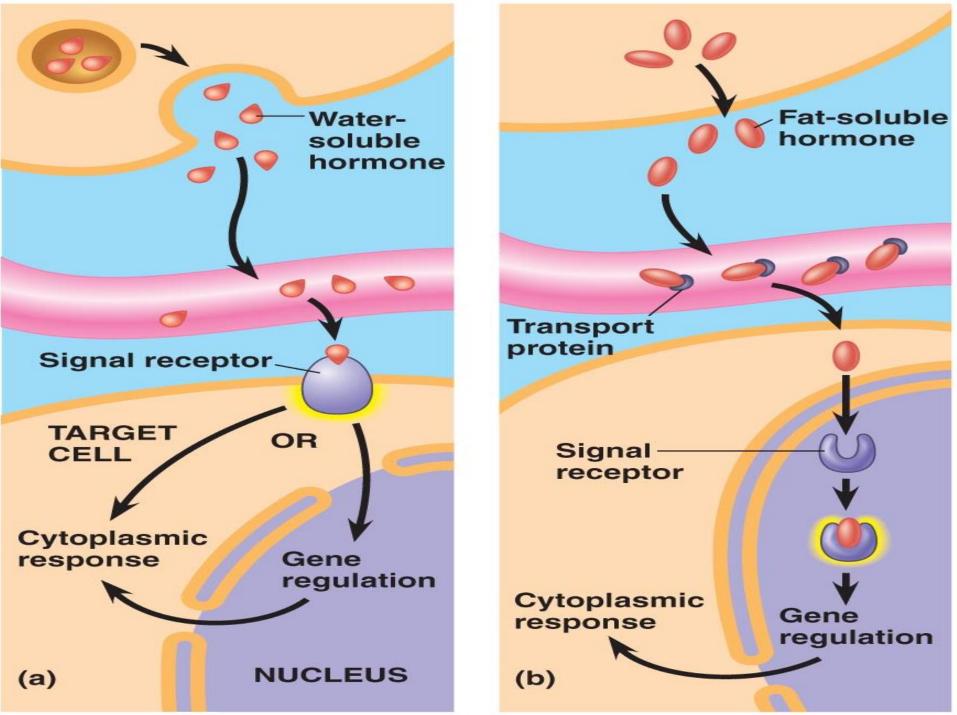

- Derived from tyrosine or tryptophan
- 3 groups

− Tyrosine ⇒ Catecholamines Behave like peptide hormones

- − Tyrosine ⇒ Thyroid hormones
 Behave like steroid hormones
- -Tryptophan \Rightarrow Melatonin

Transport of hormones

- Water soluble hormones (hydrophilic): peptides
 & catecholamines dissolved in plasma
- Fat soluble hormones (hydrophobic): Steroids and thyroid hormones transported bound to plasma proteins (90%).
 - Binding to plasma proteins helps to:
 - Provide reservoirs
 - Slow hormones clearance

Mechanism of hormone action

- In order for a target cell to respond to a hormone, specific protein receptors must be present on its plasma membrane or in its interior to which that hormone can attach.
- Only when this binding occurs can the hormone influence the working of the cell:-
 - •Hormone-receptor interaction (1st messenger)
 - •Enzyme activation
 - •Release of the second messenger
 - •Effects on cellular function

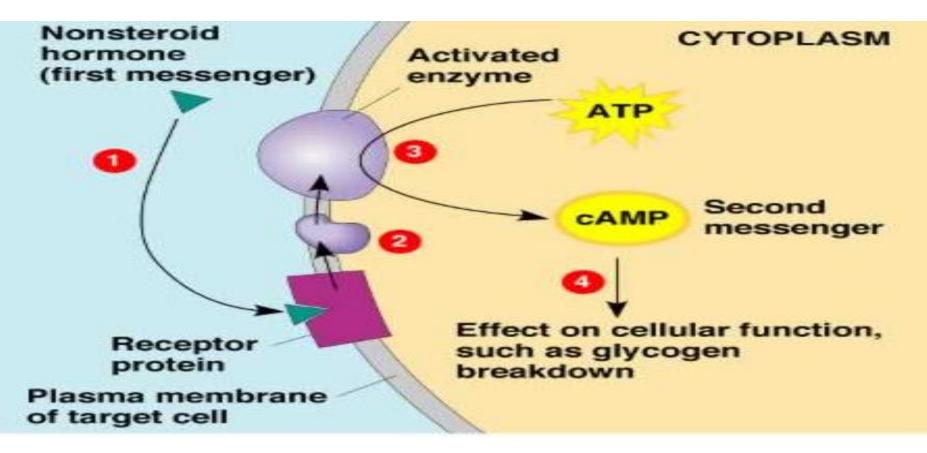

Hormone receptors

- Hormonal receptors are large proteins
- ⇒ 2000-100,000 receptors/cell
- Receptors are highly specific for a single hormone
- **C**Receptor's location:
 - On the surface of cell membrane (Proteins, Peptides hormones and catecholamines)
 - In the cell cytoplasm (Steroid hormones)
 - In the cell nucleus (Thyroid hormones)

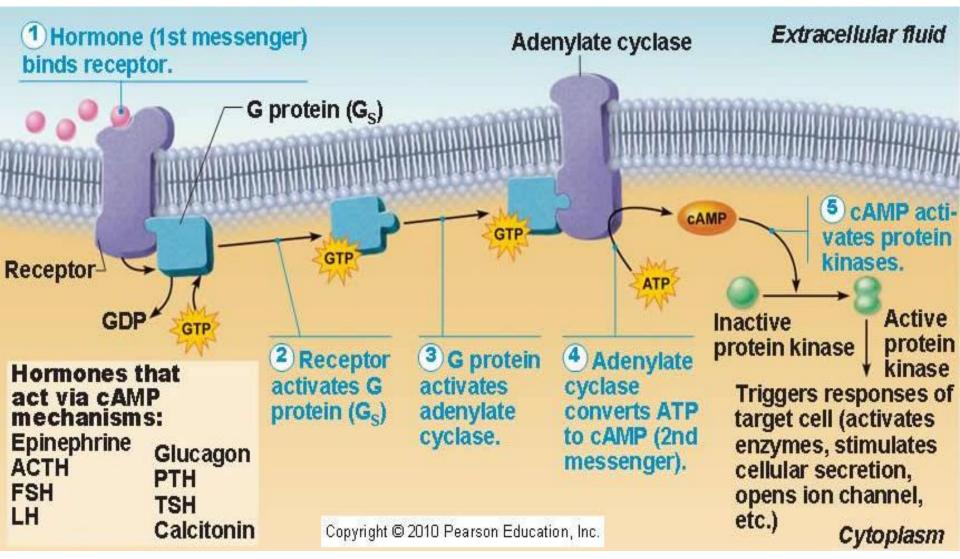

Protein and peptide hormones

Receptor on the cell membrane

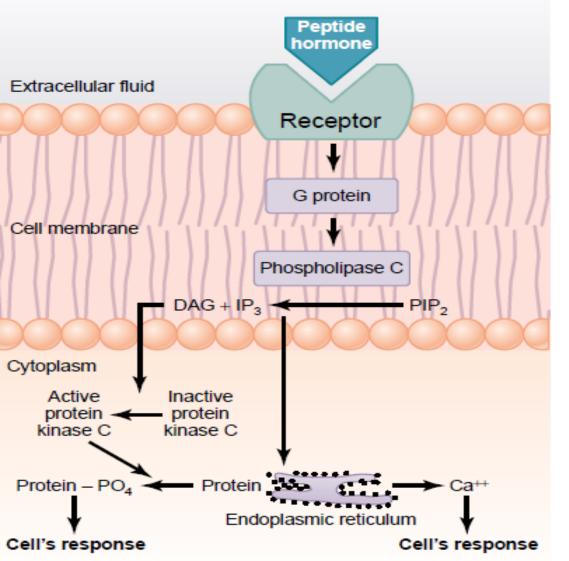

The means by which hormones exert intracellular actions is to stimulate formation of the second messenger inside the cell. The second messenger does the rest.

Second Messenger (Adynylate Cyclase – cAMP system)

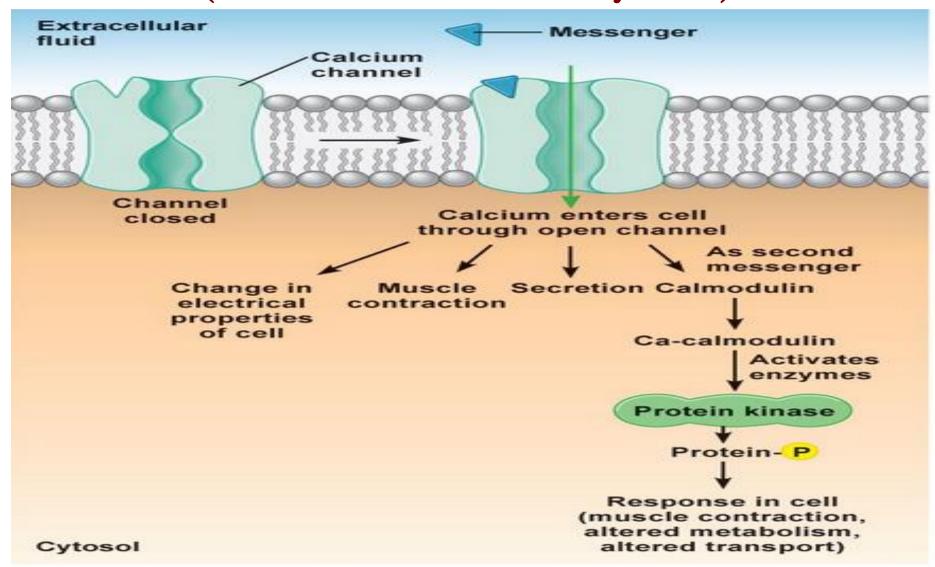

Second Messenger (Phospholipase C - IP3 system)

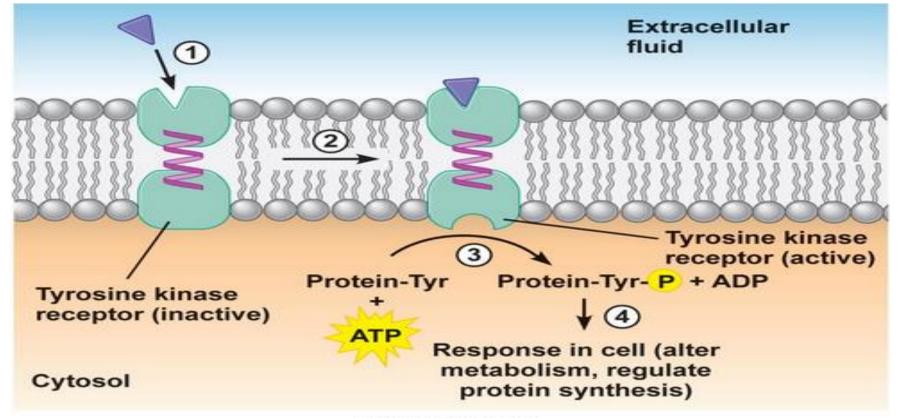

Some Hormones that use the phospholipase C second messenger system: -Angiotensin II (vascular smooth muscle) -Catecholamines (a receptors) -Gonadotropin-releasing hormone (GnRH) -Growth hormone-releasing hormone (GHRH) -Oxytocin -Thyroid-releasing hormone (TRH) -Vasopressin (V1 receptor, vascular smooth muscle)

Second Messenger (Calcium-calmodulin system)

Second Messenger (Tyrosine Kinase System)

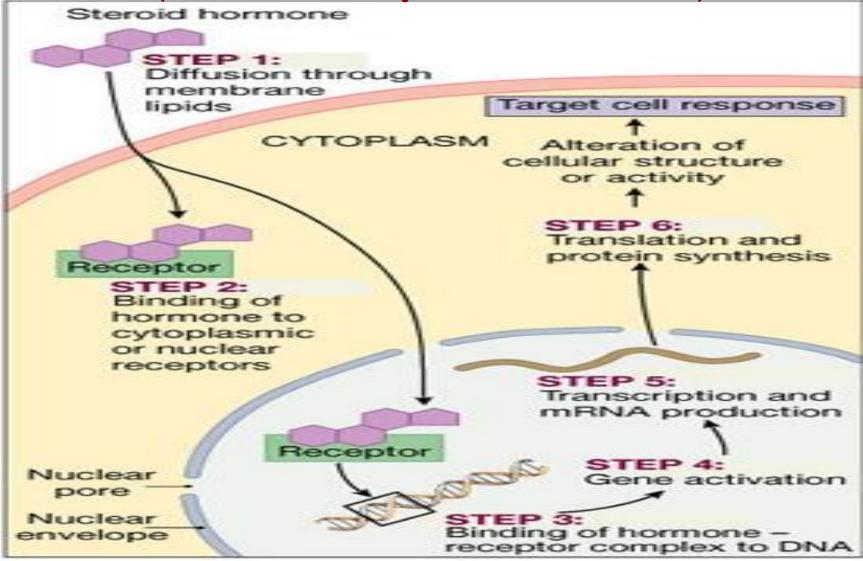

© 2011 Pearson Education, Inc.

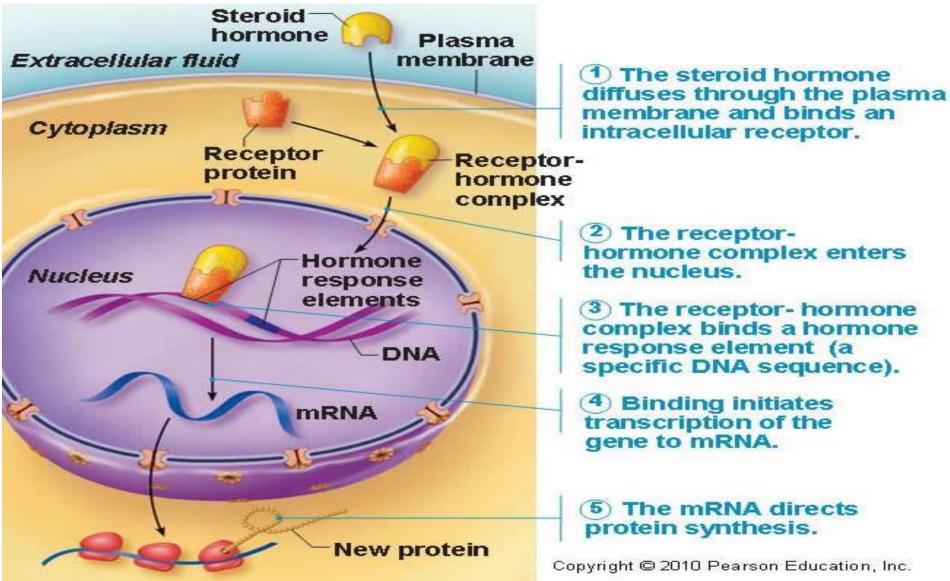

An important hormone that exerts its effects through tyrosine kinase is insulin.

Mechanism of action

(Steroid & Thyroid Hormones)

Mechanism of action (Steroid Hormones)

Regulation of hormonal receptors

0 Receptors does not remain constant

- Inactivated or destroyed
- Reactivated or manufactured
- Dose-response relationship.
- Sensitivity.
- Number.
- Affinity.

0 Down-regulation

- Increase hormone concentration leads to decrease in the number of active receptors
- Most peptide hormones have <u>pulsatile secretion</u> which prevents down regulation

0 Up-regulation

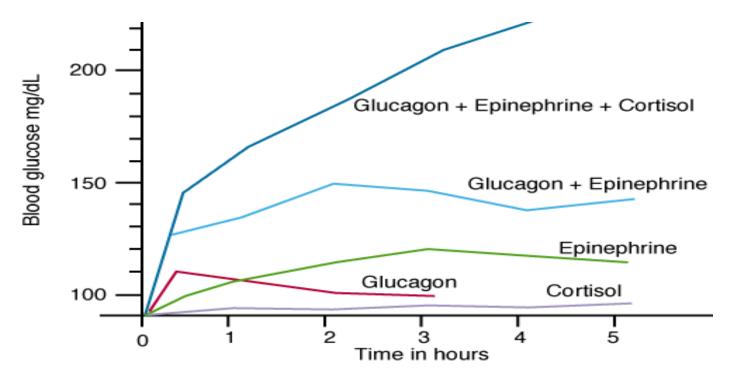

• The hormone induces greater than normal formation of a receptor or intracellular signaling proteins

Hormones interactions at

- *target cells*Multiple hormones can affect a single target simultaneously
- Three types of hormone interactions:
 - 1. Synergism
 - 2. Permissiveness
 - 3.Antagonism

- Combined action of hormones is more than just additive!
- Example: Synergistic effects of glucagon, cortisol and epinephrine on blood glucose levels.

Permissiveness

- •One hormone allows another hormone to have its full effect
 - Especially during growth
- •Example
 - Thyroid hormone have permissive effect on growth hormone action
 - Deficiency of thyroid hormone in infants leads to dwarfism.

Antagonism

- Antagonistic hormones have opposing physiological actions
 - Certain hormone diminishes the effect of other hormone
- Example
 - Glucagon antagonizes the action of insulin

Clearance of hormones

- Two factors control the concentration of a hormone in the blood:
 - 0 The rate of its secretion
 - o The rate of its removal (metabolic clearance)
- Hormones are cleared by:
 - 0 Metabolic destruction by tissues
 - 0 Binding with tissues
 - o Excretion by the liver into bile
 - Excretion by the kidney into urine
- Clearance of protein bound hormones is slower than clearance of peptide hormones
