

ANATOMY DEPARTMENT

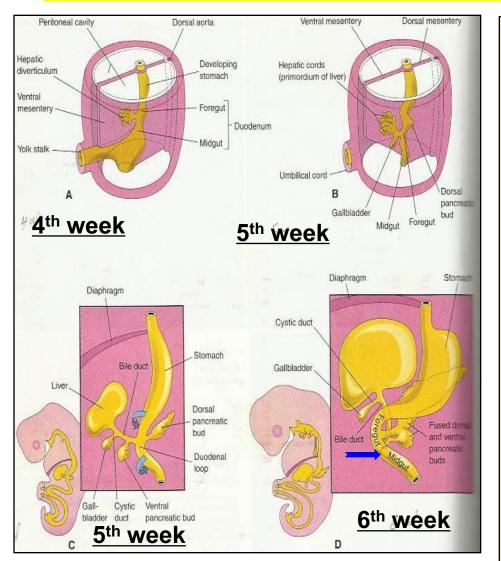

DR.SANAA AL-AISHAARAWY

DR.ESSAM Eldin Salama

OBJECTIVES

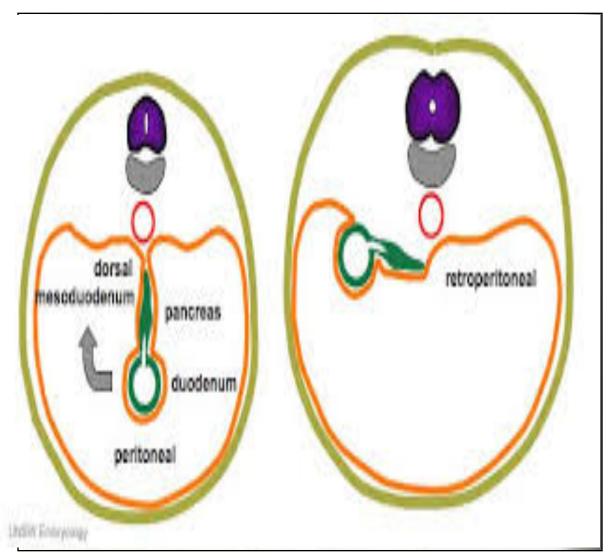

- At the end of the lecture, the students should be able to :
- Describe the development of the duodenum.
- Describe the development of the pancreas.
- Describe the development of the small intestine.
- Identify the congenital anomalies of the small intestine :
- Congenital omphalocele.
- Umbilical hernia.
- Meckel's diverticulum.

DEVELOPMENT OF THE DUODENUM

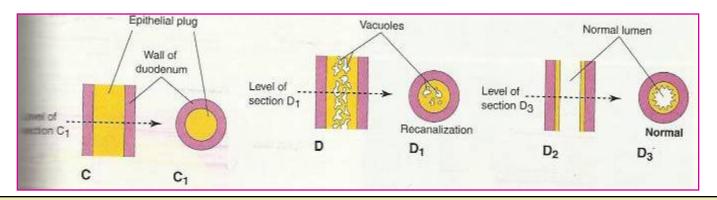

- Stages in the development of <u>duodenum</u>, liver, biliary ducts and <u>pancreas</u> (A-D).
- Early in the <u>4th week</u>, the <u>duodenum</u> develops from the endoderm of primordial gut of :
- <u>Caudal</u> part of <u>foregut</u>.
- <u>Cranial</u> part of <u>midgut</u> & from :
- Splanchnic mesoderm.
- The junction of the 2 parts of the gut <u>lies just below</u> or distal to the <u>origin of bile</u> <u>duct (C &D).</u>

DEVELOPMENT OF THE DUODENUM

- The duodenal loop is formed and projected ventrally, forming a Cshaped loop (C). The duodenal
 - **loop** is <u>rotated</u> with the stomach <u>to the</u> <u>right</u> and comes to lie on the posterior abdominal wall <u>retroperitoneally</u> with the developing pancreas.

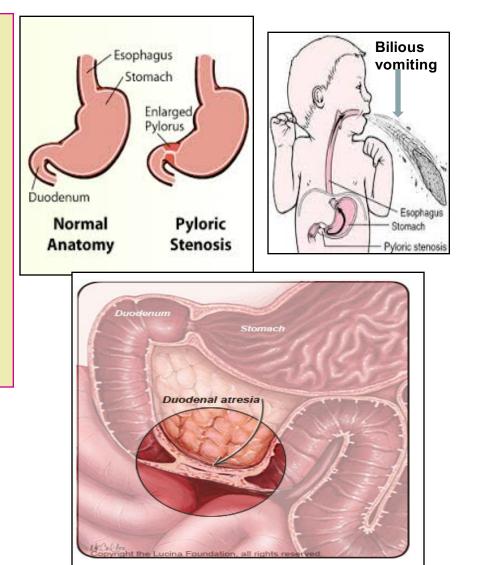

DEVELOPMENT OF THE DUODENUM

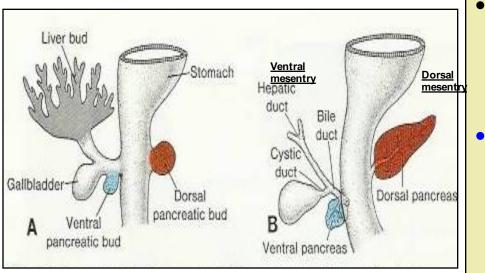

- <u>During 5th & 6th weeks</u>, the lumen of the duodenum is temporarily obliterated because of proliferation of its epithelial cells.
- Normally degeneration of epithelial cells occurs, so <u>the duodenum normally becomes</u> recanalized by <u>the end of the embryonic period (end of 8th week).</u>

Congenital anomalies

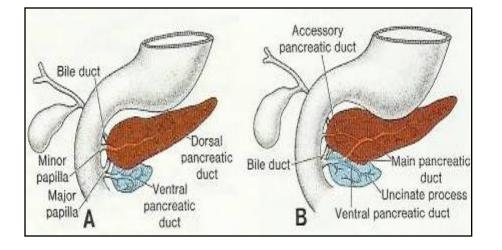

- **Duodenal stenosis**; results from incomplete recanalization of duodenum.
- Duodenal atresia; results from failure of recanalization leading to complete occlusion of the duodenal lumen, (autosomal recessive inheritance).

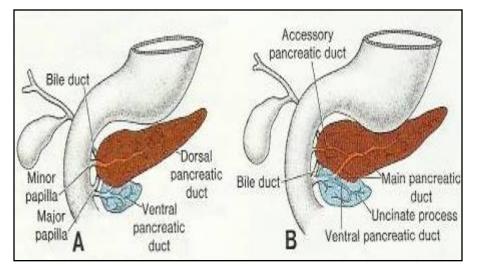

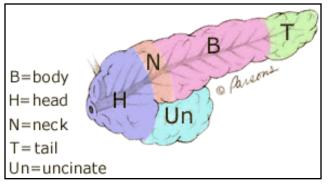

The pancreas develops from 2 buds arising from the endoderm of the caudal part of foregut :

- A ventral pancreatic bud : which develops from the proximal end of hepatic diverticulum (forms the liver & gall bladder).
- A dorsal pancreatic bud : which develops from dorsal wall of duodenum slightly cranial to the ventral bud.
- Most of pancreas is derived from the dorsal pancreatic bud.

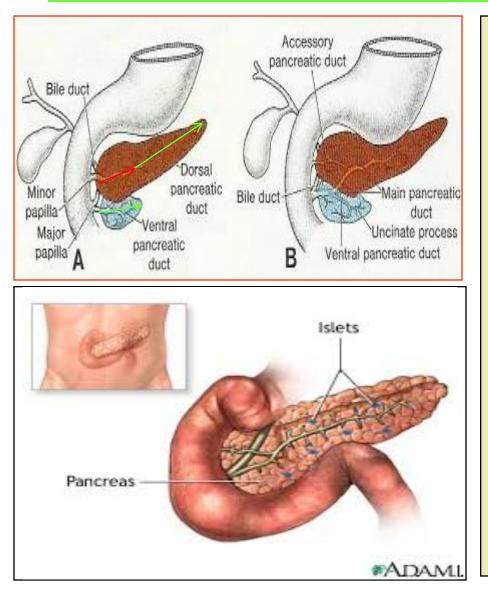

- When the duodenum rotates to the right and becomes C-shaped, the <u>ventral pancreatic bud</u> moves dorsally to lie <u>below and behind</u> the dorsal bud.
- Later the 2 buds fused together and lying in the dorsal mesentery.

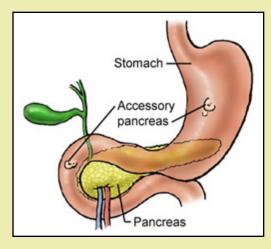

- The ventral bud forms :
- Uncinate process.
- Inferior part of head of pancreas.
- The dorsal pancreatic bud forms :
- Upper part of of head.
- Neck.
- Body &
- Tail of pancreas.

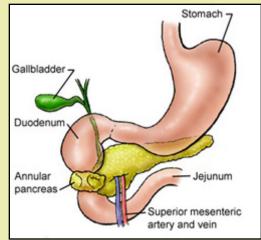

- The main pancreatic duct is formed from :
- The duct of the ventral bud.
- The distal part of duct of dorsal bud.
- The accessory pancreatic duct is derived from :
- Proximal part of duct of dorsal bud.
- The parenchyma of pancreas is derived from the endoderm of pancreatic buds.
- Pancreatic islets develops from parenchymatous pancreatic tissue.
- Insuline secretion begins at 5th month of pregnancy.

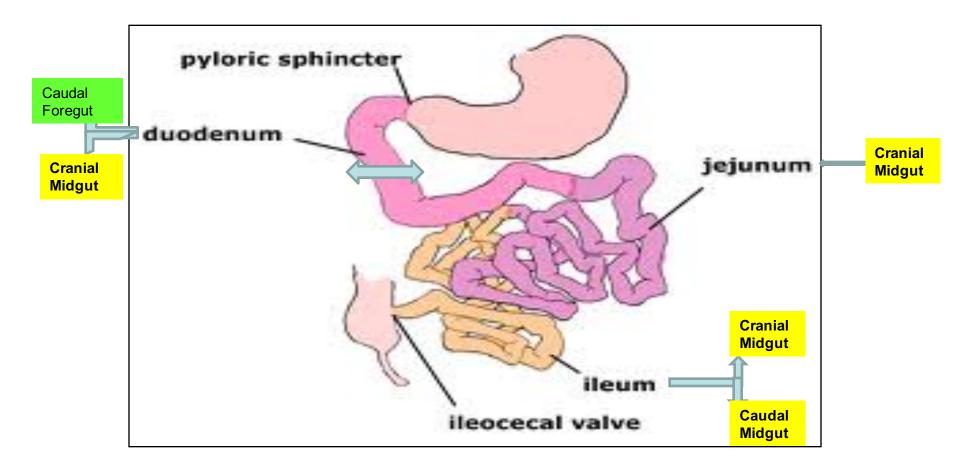

Congenital anomalies

- Accessory pancreatic tissue; located in the wall of the stomach <u>or</u> duodenum.
- Anular pancreas; a thin flat <u>band of pancreatic</u> <u>tissue</u> surrounding <u>the second part of the</u> <u>duodenum</u>, causing <u>duodenal obstruction</u>.

DEVELOPMENT OF SMALL INTESTINE

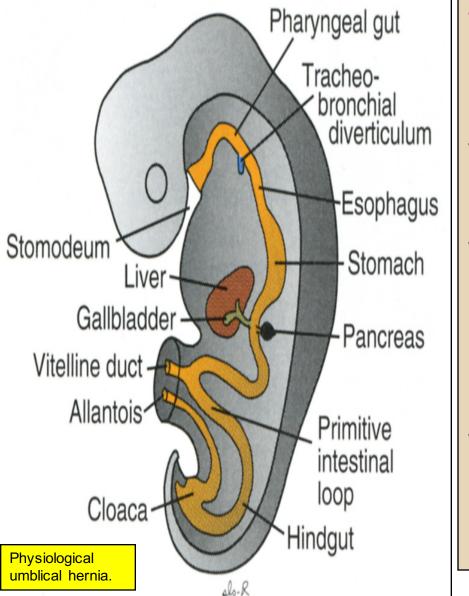

DEVELOPMENT OF SMALL INTESTINE

- Derivatives of cranial part of the midgut loop :
- <u>Distal</u> part of the <u>duodenum</u> (<u>proximal</u> part of <u>duodenum</u> is developed from <u>caudal part of foregut</u>)
- Jejunum
- Upper part of the ileum.
- Derivatives of the <u>caudal part</u> of midgut loop :
- Lower portion of ileum.
- Cecum & appendix.
- Ascending colon + proximal 2/3 of transverse colon.
- So, the small intestine is developed from :
- Caudal part of foregut.
- All midgut.
- Midgut is supplied by superior mesenteric artey (artery of midgut).

STAGES OF DEVELOPMENT OF SMALL INTESTINE

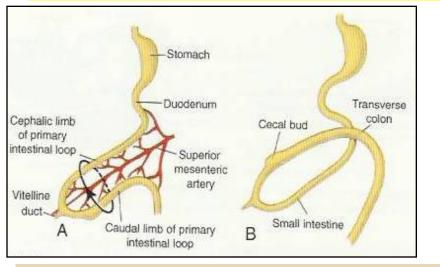

- Preherniation stage.
- Stage of physiological umbilical hernia.
- stage of <u>rotation</u> of midgut loop.
- Stage of <u>reduction of umbilical hernia.</u>
- Stage of <u>fixation</u> of various parts <u>of</u> <u>intestine</u>.

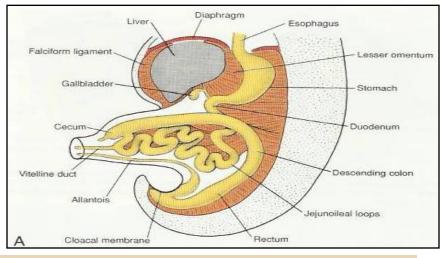

Development of midgut loop

- At the biginning of <u>6th week</u>, the midgut elongates to form a <u>venteral U-shaped midgut</u> <u>loop.</u>
- Midgut loop communicates with the yolk sac by vitelline duct or yolk stalk.
- As a result of rapidly growing liver, kidneys & gut ,the abdominal cavity is temporarily too small to contain the developing rapidly growing intestinal loop.
- So ,Midgut loop projects into the <u>umbilical cord</u> ...this is called physiological umbilical herniation (begins at 6th w.).

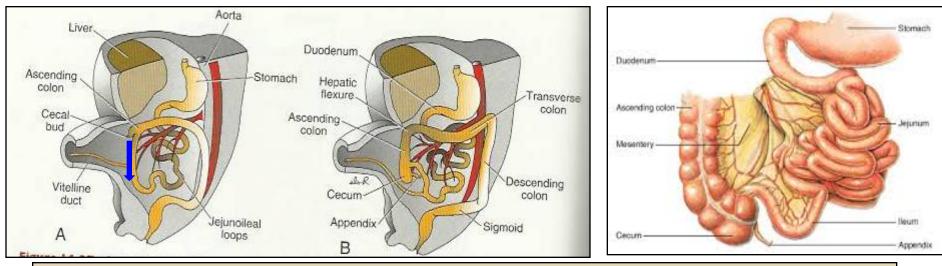

ROTATION OF THE MIDGUT LOOP

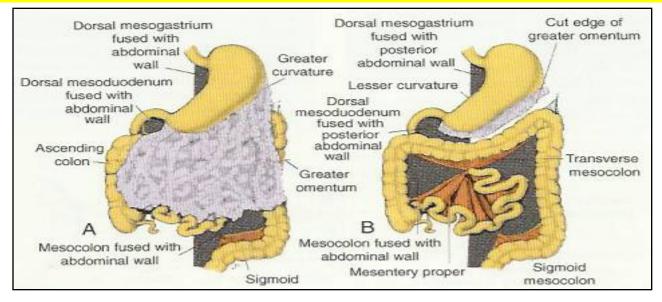

- Midgut loop has a <u>cranial limb</u> & a <u>caudal limb.</u>
- Midgut loop <u>rotates around</u> the axis of the <u>superior mesenteric artery</u>.
- Midgut loop rotates first 90 degrees to bring the <u>cranial limb</u> to the <u>right</u> and caudal limb to left <u>during the physiological hernia.</u>
- <u>The cranial limb of midgut loop elongates to form the intestinal</u> coiled loops (jejunum & ileum).
- This rotation is counterclockwise and it is completed to 270 degrees, so <u>after reduction of physiological hernia</u> it rotates to about 180 degrees.

RETURN OF MIDGUT TO ABDOMEN

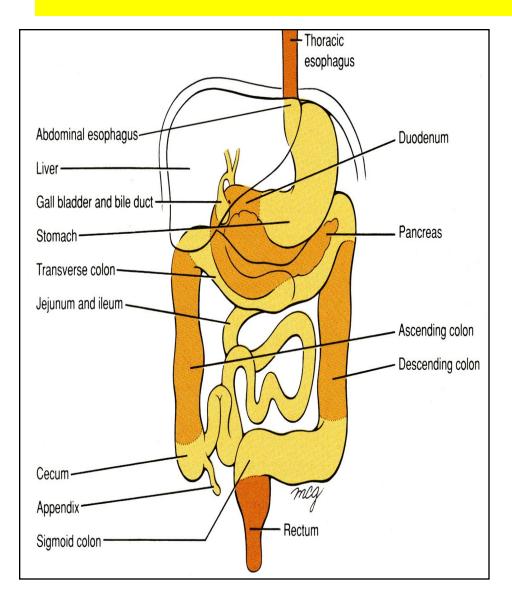

- <u>During 10th week</u>, the intestines return to the abdomen due to regression of liver & kidneys + expansion of abdominal cavity. It is called reduction of physiological midgut hernia.
- <u>Rotation is completed</u> and the <u>coiled intestinal loops</u> lie in their final position in <u>the left side.</u>
- The caecum <u>at first lies</u> below the liver, <u>but later</u> it descends to lie in the right iliac fossa.

FIXATION OF VARIOUS PARTS OF INTESTINE

- The mesentry of jejunoileal loops is at first continuous with that of the ascending colon.
- When the mesentry of ascending colon fuses with the posterior abdominal wall, the mesentry of small intestine becomes fan-shaped and acquires a <u>new line of attachment</u> that passes from <u>duodenojejunal junction</u> to the <u>ileocecal</u> junction.

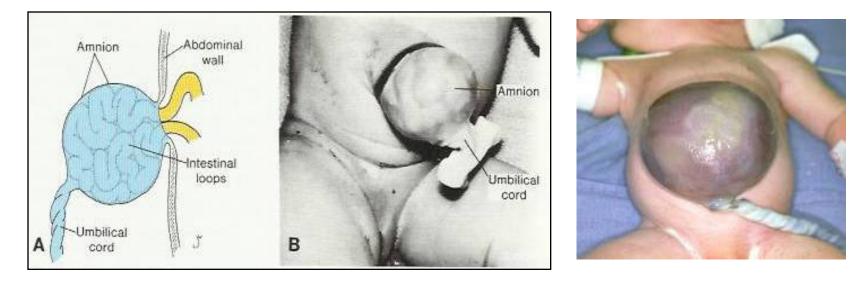

Fixation of various parts of intestines

The enlarged colon presses the <u>duodenum & pancreas against the posterior abdominal wall</u>.
C & F

Most of duodenal mesentery is absorbed, <u>so most of duodenum</u> (except for about the first 2.5 cm derived from foregut) <u>& pancreas</u> become retroperitoneal. C & F

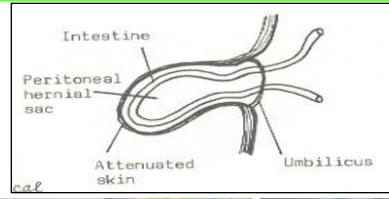

Congenital Omphalocele

- It is a persistence of herniation of abdominal contents into proximal part of umbilical cord due to <u>failure of reduction of</u> <u>physiological hernia to abdominal cavity at 10th week.</u>
- Herniation of <u>intestines</u> occurs in 1 of 5000 births herniation of <u>liver & intestines</u> occurs in 1 of 10,000 births.
- It is accompanied by small abdominal cavity.
- <u>The hernial sac is covered by</u> the epithelium of the umbilical cord/or the amnion.
- Immediate surgical repair is required.

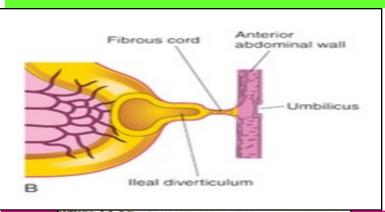

Congenital Umbilical Hernia

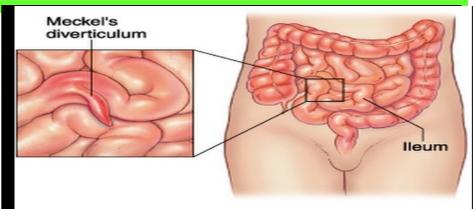

- The intestines <u>return to</u> <u>abdominal cavity at 10th</u> week, but herniate through an <u>imperfectly closed umbilicus</u>
- It is a <u>common type</u> of hernia.
- The herniated contents are usually the greater omentum & small intestine.
- <u>The hernial sac is covered</u> by skin & subcutaneous tissue.
- It protrudes during crying,straining or coughing and <u>can be easily reduced</u> through fibrous ring at umbilicus.
- Surgery is performed <u>at age of</u> <u>3-5 years.</u>

lleal (Meckel's) Diverticulum

- It is one of the most common anomalies of the digestive tract, present in about 2% -4% of people, more common in males.
- It is a small pouch from the ileum, and may contain small patches of gastric & pancreatic tissues causing ulceration, bleeding or even perforation.
- <u>It is the remnant of proximal part</u> **nonobliterated part of yolk stalk** (or vitelline duct).
- It arises from <u>antimesenteric border of ileum</u>, 1/2 meter from ileocecal junction.
- It is sometimes becomes inflammed and causes <u>symptoms that</u> <u>mimic appendicitis.</u>
- It may be <u>connected to the umbilucus by a fibrous cord</u>, or <u>the middle</u> <u>portion forms a cyst</u> or <u>may remain patent</u> forming the fistula so, faecal matter is carried through the duct into umbilicus.

THANK YOU

SUMMARY

- The foregut gives rise to :
- **Duodenum** (proximal to the opening of the bile duct).
- Pancreas.
- Biliary apparatus.
- The pancreas develops from :
- Dorsal & ventral pancreatic buds <u>that</u> <u>develop from</u> the endodermal lining of the caudal part of foregut.

SUMMARY

The midgut gives rise to

The small intestine :

- **Duodenum** (distal to bile duct).
- Jejunum & ileum.
- physiological umbilical hernia :
 - The midgut forms a U-shaped intestinal loop that herniates into the umbilical cord during 6th week.
- **Omphalocele** results from failure of return of the intestine into the abdomen.
- Yolk stalk: A narrow tube present in the early embryo that connects the midgut of the embryo to the yolk sac outside the embryo through the umbilical opening.
- It is usually obliterated, but a remnant of it may persist: most commonly as a finger-like protrusion from the small intestine known as Meckelis diverticulum.
- **Ileal diverticula** are common; however, only a few of them become inflamed and produce pain.
