KING SAUD UNIVERSITY

Drugs used in management of pain

Objectives:

- Revise how pain is perceived and modulated, emphasizing on neurotransmitters, receptors, channels involved
- **Classify drugs used in management of pain**
- Expand on pharmacology of opiates, patterns of classification, mechanism of action , indications, ADR,...etc. detailing on **morphine** as an example & its synthetic derivatives.
- **Hints on the properties & clinical uses of morphine antagonists.**
- Compare in brief actions and indications of other opiate agonists and antagonists.

color index:

- extra information and further explanation
- **important**
- **doctors notes**
- **Drugs names**
- **Mnemonics**

Overview

NSAIDs

- 1st class of drugs used.
 - work at the site of tissue (**act peripherally**)
 - so decreasing opioid-related side effects.
 - Neither cause tolerance or dependence.
 - Has a ceiling effect to analgesia.
- NSAIDS are anti inflammatory therefore they prevent formation of the chemical mediators associated with nociceptor activation

Adjuvant drugs

modify the perception of pain and remove the concomitants of pain such as anxiety, fear, depression.

They don't really stop the pain rather they work on managing it via controlling symptoms
Primarily indicated for clinical conditions other than pain

Antiepileptics

Antidepressants

neuroleptic

anxiolytics

Opioids

Receptors (g protein coupled r)

1. Mu (μ).
2. Kappa (κ)
3. Delta (δ)
4. ORL-1.

their source

1. Natural → **Morphine, Codeine**
2. Semisynthetic → **Heroin**
3. Synthetic → **Pethidine, Methadone**

classification according to

agonistic/antagonistic action

Agonists Morphine, Codeine, Pethidine, Methadone

Mixed agonist/antagonist Pentazocine

Pure antagonist Nalaxone, Naltraxone

their specificity of action on receptors

μ receptor. agonists → Morphine, codeine, heroin
agonist at k receptor. & antagonist at μ receptor. → Pentazocine

To understand !

A case of overdose:

Sigmund Freud, the father of psychoanalysis. His cancer of the jaw was causing him increasingly severe PAIN & agony. He begged his friend and doctor, Max Schur to relieve him. His doctor administered increasing doses of MORPHINE that resulted in Freud's death on 23 September 1939.

What effect of morphine caused the death of Sigmund Freud? Euthenasia

What is pain?

-The 5th vital sign suggests that assessment of pain should be as automatic as taking a client's BP and pulse

-Is an unpleasant sensory and emotional experience associated with actual and potential tissue damage, or described in terms of such damage

Why should we treat pain?

- Pain is a miserable experience.
- Pain is the most common reason patient seek medical advice.
- Impairs the patient functional ability & psychological well being.
- Pain increases :
 - sympathetic output.
 - Increases myocardial oxygen demand. May cause myocardial infraction.
 - Increases BP, HR.
- Pain limits mobility.
- Increases risk for DVT (Deep vein thrombosis) and PE (Pulmonary embolism)

Drugs used in management of pain:

We use Adjuvant drugs and NSAIDs in order to relieve.

Adjuvant drugs

- May modify the perception of pain (by ↓ AP) and remove the concomitants of pain such as anxiety, fear, depression.
- Primarily indicated for clinical conditions other than pain. They're indicated for anxiety-epilepsy-depression.
- e.g. Anxiolytics, Neuroleptics, Antidepressants, Antiepileptics. Used in sever + chronic pains
- Useful in neuropathic pain

Opioids

- Opium is derived from the juice of the opium poppy, Papaver somniferum
- The natural products include morphine, codeine, papaverine and thebaine
- Opiates are drugs derived from opium and semisynthetic and synthetic derivatives
- Opioids refer to opiates and Endogenous opioid peptides, e.g. β- Endorphins, enkephalins & dynorphins.
- Opioids are natural, semi- synthetic, or synthetic compounds that produce morphine-like effects.
- Uses: Their primary use is to relieve intense pain, whether that pain results from surgery, injury, or chronic disease.

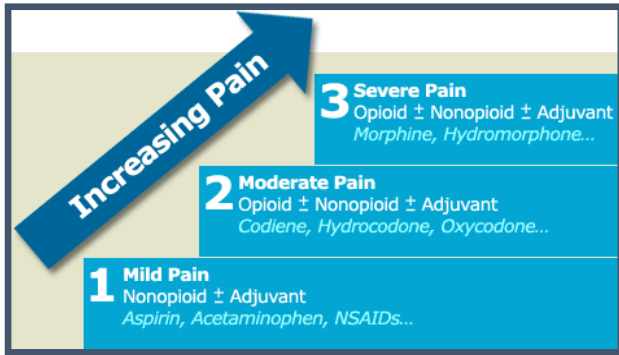

NSAIDs

- Generally the first class of drugs used for controlling pain.
- Work at site of tissue injury to prevent the formation of the nociceptive mediators As histamine and prostaglandin.
- Can decrease opioid use by ~30% therefore decreasing opioid-related side effects.
- They neither cause tolerance or dependence
- Has a ceiling effect to analgesia. They have a limit then if the pain increase than this limit NSAID produce No effect to relief the pain even if we increase the dose.

Opioids

WHO Pain Ladder:

Why do we use more than 1 drug? → Combination of drugs lowers the ADRs

If the combination failed because of increasing in the severity of the pain then we add strong Opioid.

If these drugs failed to control pain then we have to add mild or weak Opioid.

كل شيء له ثمن، فإذا أبغى أقضي
أو أقلل الألم راح أضطر أزود الأدوية
وجرعاتها فبالتالي زدت معها
الأثار الجانبية

What's the advantages and disadvantages for this combination?

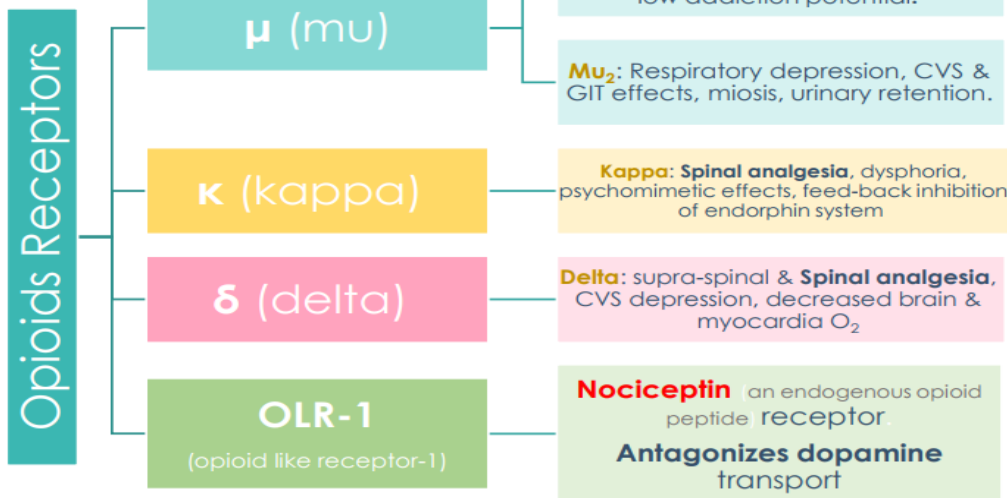

Advantages: NSAIDs, they're not addictive and they aren't cause tolerance.

Disadvantages: they can only relieve mild to moderate pain they can't relieve severe pain e.g. pain of trauma – pain of cancer.

Opioids exert their pharmacological receptors through 4 types

of receptors: These receptor mainly found in the CNS and less in peripheral

435team

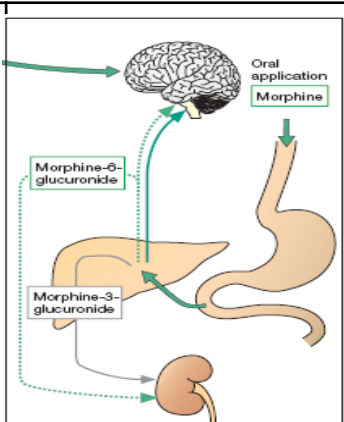

- All of the 4 receptors are typical **G-protein coupled** receptors.

- Anatomical distribution in brain, spinal cord, & the periphery.

Classification :

A- According to their source:		
1- Natural: Morphine Codeine	2- Semi-synthetic: Heroin → (Diacetylmorphine, synthesized form morphine)	3- Synthetic: Pethidine, Methadone.
B- According to their specificity of action on receptors:		
Morphine, codeine, heroin → μ -receptor agonists		Pentazocine → agonist at κ -receptors → antagonist at μ -receptors
C- According to agonistic/antagonistic actions:		
1- Agonists; Morphine, Codeine, Pethidine, Methadone	2- Mixed agonists /antagonists; Pentazocine	3- Pure antagonist; Nalaxone, Naltraxone

Opioids

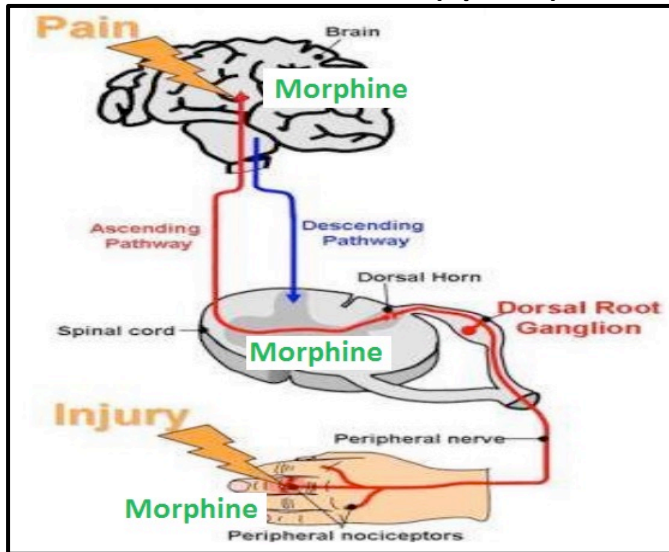

Drug	morphine	
Mech. of action	<ol style="list-style-type: none"> 1. Binding to presynaptic opioid receptors coupled to Gi (inhibitory G protein) → ↓ AC (adenylate cyclase) & cAMP → ↓ N-type voltage-gated Ca²⁺ channels (inhibit influx of Ca²⁺, → reduce release of neurotransmitter) → ↓ excitatory transmitter. 2. Binding to postsynaptic receptors → opening of K channels. (↑ postsynaptic K⁺ efflux (hyperpolarization)) → ↓ neuronal excitability. Decrease release of neurotransmitter from presynaptic and decrease the neuronal activity of post synaptic leading decrease in action potential signals of pain. 	
Pharmacodynamics Actions	<ul style="list-style-type: none"> - Analgesia [in acute & chronic pain] more effective on visceral & skeletal pain. - Euphoria & sedation. → relieves anxiety of patient. → that's why they may addict it. - Respiratory depression → by reduction of the sensitivity of respiratory center neurons to carbon di- oxide. Main cause of death in addicted people - Depression of cough reflexes → treatment of non-reproductive cough. Dry cough. - Nausea & vomiting → ↑ excitation CRTZ . This is the vomiting center in the brain.(Stimulate vomiting). - Pin point pupil (miosis) → Diagnostic feature of opioid addiction. <ul style="list-style-type: none"> - How? It excites the EWN → enhance parasympathetic effect → constrict pupil. - Releases histamine from mast cells → causing: hypotension, bronchoconstriction, itching of skin → contraindicated w\ asthmatic pts. - Effects on GIT:- • ↑ in tone of contraction , ↓ motility of intestine → severe constipation → In GIT reduces motility (peristalsis) by reducing release of Ach → used to treat diarrhea. <ul style="list-style-type: none"> • ↑ biliary tract pressure and biliary colic due to contraction of the gallbladder and constriction of the biliary sphincter → contraindicated in biliary colic. increase the intra-biliary pressure so for this reason we can't use it for gallbladder colic. - Depress renal functions 	
Tolerance	<ul style="list-style-type: none"> - Tolerance occurs when the person takes a higher dose of the drug to achieve the same level of response achieved initially - Occurs rapidly with opioids (e.g. morphine 12–24 hours) - Develops to (reduce) respiratory depression, analgesia, euphoria and sedation. No tolerance for miosis so it's good indicator for addict people. 	
Dependence	<ul style="list-style-type: none"> - Dependence develops when the neurons adapt to the repeated drug exposure and only function normally in the presence of the drug - Physical dependence (abstinence) → withdrawal manifestations develop upon stoppage. Or giving opioids antagonist. - Lasts for a few days (8-10 days) in form of ↑ body ache, insomnia, diarrhea, goose flesh, lacrimation. - Psychological dependence lasting for months / years → craving. This is very difficult to treat. - Dependence developed mainly with morphine. 	
Pharmacokinetics	<ul style="list-style-type: none"> - T 1/2 is 2-3 h - It is slowly and erratically absorbed orally (bioavailability 10-40%) → Given SC, IM, or IV injection. - Metabolized by conjugation with glucuronic acid It goes to the intestine (undergo recycling) then it goes back to the blood circulation. - Undergoes enterohepatic recycling → Crosses BBB. - Crosses Placenta → Infants born of addicted mothers show physical dependence on opiates and exhibit withdrawal symptoms if opioids are not administered if the mother got addictive to morphine, the newborn baby will also be addictive to morphine. 	 <p>The diagram illustrates the metabolism of morphine. It starts with 'Oral application Morphine' entering the stomach and small intestine. An arrow points to the liver, where morphine is metabolized into 'Morphine-3-glucuronide' and 'Morphine-6-glucuronide'. A dashed arrow shows 'Morphine-3-glucuronide' being reabsorbed in the intestine and returning to the liver, representing enterohepatic recycling. Another arrow shows 'Morphine-6-glucuronide' being excreted in the urine. A final arrow points from the liver to the brain, indicating that morphine crosses the blood-brain barrier.</p>

Opioids con.

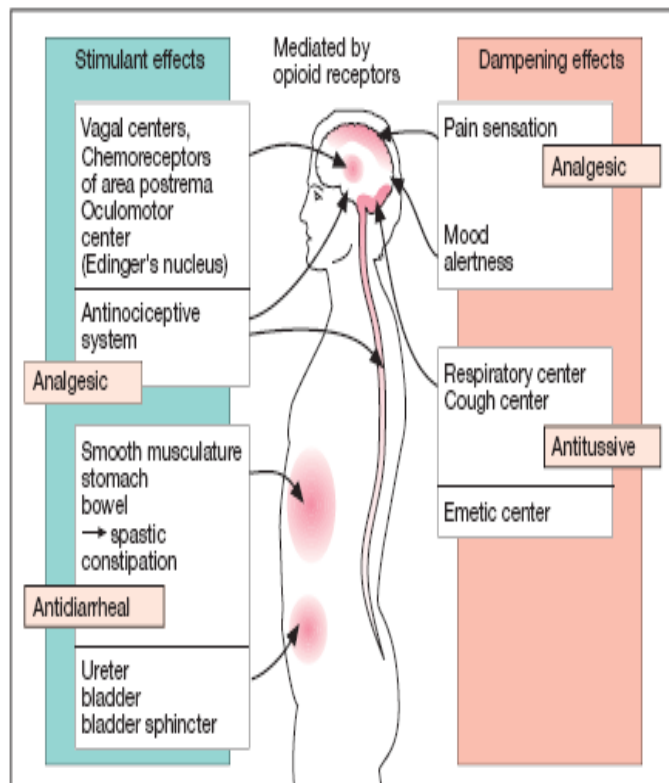

Drug	morphine		
Clinical Indications	<ol style="list-style-type: none"> Pain Control : cancer pain, severe burns, trauma, Severe visceral pain (not renalcolics (because it constricts the ureter) /biliary colics, acute pancreatitis because the gall bladder & pancreas has similar sphincter constricted by morphine) Myocardial Ischemia and Acute Pulmonary Edema Relief: distress : e.g. heart failure (non painful conditions) Pre- anesthetic medication <p style="text-align: right; color: green;">*morphine release histamine, so it can cause bronchoconstriction and centrally depresses respiration.</p>		
Adverse Effects	<ul style="list-style-type: none"> - Constipation - Respiratory Depression - Itching - Nausea /Vomiting - Constricted Pupil - Sedation <p>➤ (CRINCS)</p>	Contraindications	<ul style="list-style-type: none"> - Head Injury dilation in cranial blood vessels > intra-cranial Pressure >bleeding - Bronchial asthma or Impaired Pulmonary Function - Biliary colic →it increase the pressure of biliary tract. - Elderly : more sensitive due to →↓ Metabolism, lean body mass& Renal function - Pancreatic pain - Pts take MAOIs (Monoamine oxidase inhibitors) →bc depressant actions of morphine are enhanced - Infants, neonates, or during child birth→ decrease conjugating capacity → accumulate→ respiratory depression

Better understanding

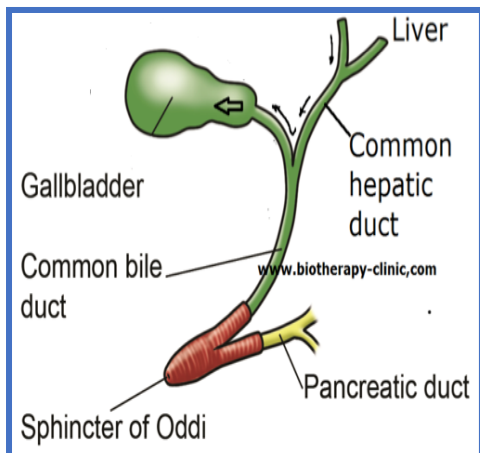

Mechanism of action (opioids)

Pharmacological action of morphine

B. Effects of opioids

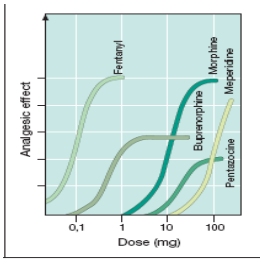

Opioids

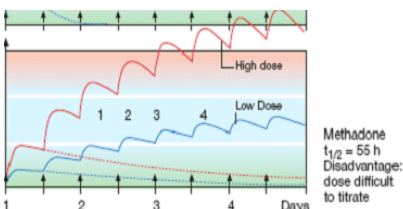

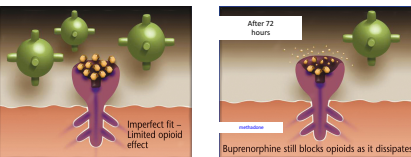

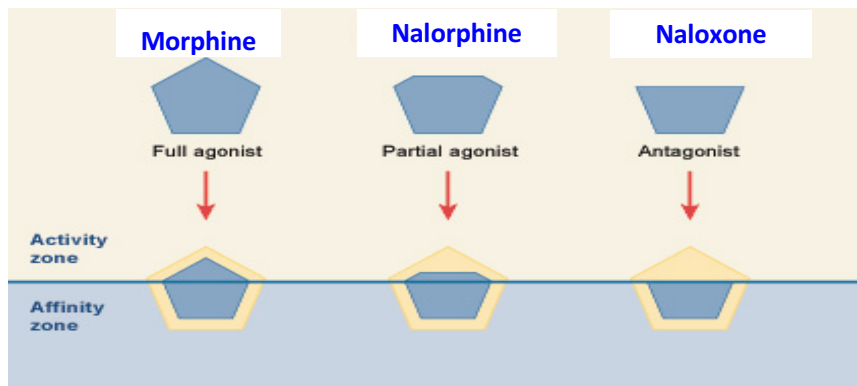

Opioid drugs:

Drug	Codeine
Characteristics	<ul style="list-style-type: none"> • μ Agonist • Dependence less than morphine
Indication	<ul style="list-style-type: none"> • Used in mild & moderate pain (systemic) • Dry cough • Diarrhea

Opioid Agonists:

Drug	TRAMADOL	PETHIDINE (meperidine)	FENTANYL
Mechanism of action	<ul style="list-style-type: none"> • Synthetic, μ agonist. • less potent than Morphine. \rightarrowso it is weak Analgesic. • inhibits NE and 5HT (serotonin) reuptake. 	<p>Synthetic, more effective k (kappa) agonist.</p> <div style="background-color: #FFD700; text-align: center; padding: 5px;">Pharmacodynamics</div> <ul style="list-style-type: none"> - Less analgesic, constipating, depressant on fetal respiration than morphine. - No cough suppressant effect. - Does not cause pinpoint pupils but, rather, causes the pupils to dilate because of an anticholinergic action. 	<ul style="list-style-type: none"> • Synthetic, μ agonist, • more potent than Pethidine and Morphine  <p style="font-size: small; text-align: center;">B. Opioids: dose-response relationship</p>
P.K	Can be given orally \rightarrow more oral bioavailability	—	<ul style="list-style-type: none"> • Highly lipophilic. • Short Duration.
Indications	<ul style="list-style-type: none"> • Mild to moderate acute and chronic visceral pain. • During labor \rightarrow because it does not inhibit respiration. 	<ul style="list-style-type: none"> • As in Morphine but not in cough and diarrhea. • Better \rightarrowpreanaesthetic medication. • Used in obstetric analgesia (no decrease in respiration) • Used in severe visceral pain; renal and biliary colics (smooth muscles relaxant). <ul style="list-style-type: none"> - Used for acute pain. <p style="font-size: small; color: green;">Pethidine is metabolized by dealkylation for this reason it doesn't accumulate in the body of the fetus so, it won't cause respiratory depression in the fetus.</p> <ul style="list-style-type: none"> • Has atropine-like action (smooth muscle relaxant) so we can use it with biliary colic and pancreatitis. 	<ul style="list-style-type: none"> • Analgesic supplement during anesthesia (IV or intrathecal = injection into the spinal canal). • Induce and maintain anesthesia in poor-risk pts (stabilizing heart) • Used in combination with Droperidol as NEUROLEPTANALGESIA. - In cancer pain and severe postoperative pain; (transdermal patch changed every 72 hrs)  <p style="color: green; font-size: small;">لصفقه تخدر كل الجسم و يتم تغييرها كل ٣ أيام</p>
ADRs	<ul style="list-style-type: none"> - Seizures (not use with epileptics) - Nausea - Dry mouth - Dizziness - Sedation - Less ADRs on respiratory and CVS 	<ul style="list-style-type: none"> - Tremors, convulsions is due to the serotonin in the brain, hyperthermia, hypotension. - Blurred vision, dry mouth, urine retention (atropine-like effects) - Tolerance and addiction. 	<ul style="list-style-type: none"> - Respiratory depression (most serious) - CV effects are less. So it is good for pts with heart problems. - Bradycardia may still occur

Opioids

Drug	Opioid agonists	Opioid Antagonists	
	METHADONE	NALOXONE	NALTREXONE
Action/Mech. of action	<p>- Weaker synthetic μ agonist.</p> <p>- antagonist of the N-methyl- D-aspartate (NMDA) receptor.</p>	<p>Use for overdose of morphine (antidote)</p> <p>- Pure opioid antagonist</p> <p>- Competitive antagonist to μ, κ, and δ.</p>	<p>Very similar to Naloxone</p>
P.D	In non-addicts, it causes tolerance and dependence but not as severe as that of Morphine .	—	—
P.K	T1/2 = 55 hrs	Effects lasts only for 2-4 hrs.	Longer duration of action. T1/2 = 10hrs
Indications	<p>Used to treat and control opioid withdrawal (in people who have become addicted to opiates such as heroin)</p> <p>neurogenic pain \rightarrow NMDA antagonist.</p> 	<ul style="list-style-type: none"> Used to treat and reverse respiratory depression caused by opioid overdose. Reverse the effect of analgesia on the respiration of the new born baby. Precipitates withdrawal syndrome in addicts. 	
	<p>With addition of opioid:</p>  <p>With methadone:</p> 	<p>OPIOID ANTAGONISTS It is better to be pure either Agonist or Antagonist</p> 	

إِنَّ فِي ذَلِكَ لَآيَاتٍ لِّقَوْمٍ يَتَفَكَّرُونَ ﴿٣﴾
