Management of diabetic ketoacidosis and hypoglycemia

Prof. Hanan Hagar

- Is a serious acute emergency situation that requires admission to hospital with a risk of death.
- It develops as a result of insulin deficiency
- It is a characteristic feature of type I diabetes but may occur with type II especially during stress.

In absence of insulin, many metabolic changes can occur:

Carbohydrates

- − ↑ Glycogenolysis
- − ↑ Gluconeogenesis

In absence of insulin,

Protein

† proteolysis thus providing amino acid as precursors for gluconeogenesis.

In absence of insulin,

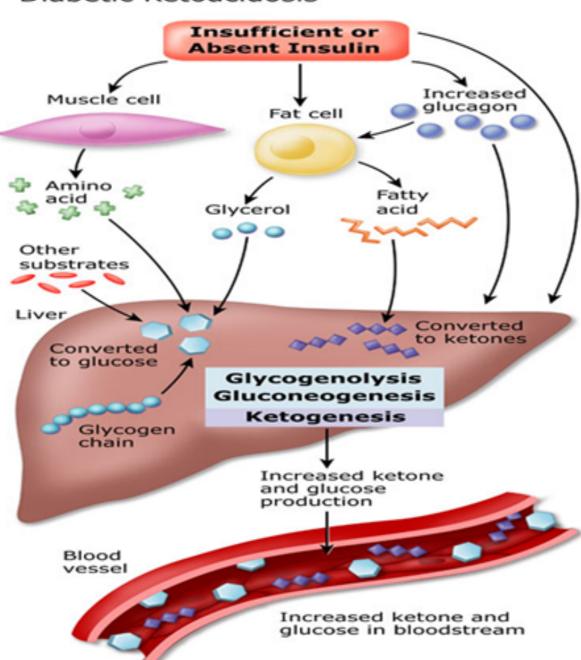

Fats:

Lipolysis & ketogenesis

Fat breakdown to <u>free fatty acids</u> then to acetyl-CoA that is converted to ketone bodies

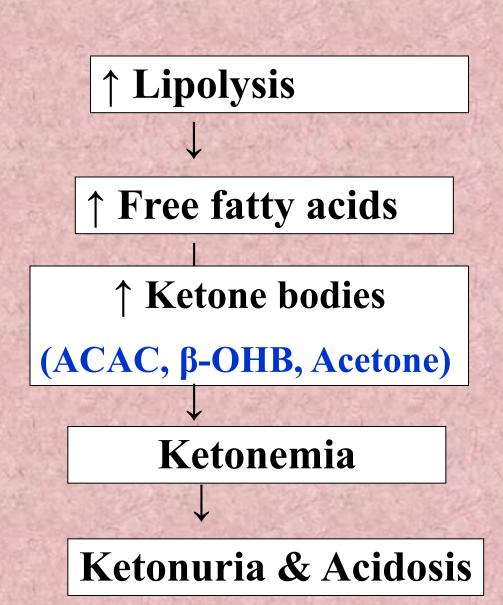

Acetoacetic acid, β-hydroxybutyric acid and acetone (↑ ketogenesis).

Insulin deficiency

Insulin deficiency

glycogenolysis † gluconeogenesis, protein catabolism Lipolysis Hyperglycemia Glycosuria **Osmotic diuresis Dehydration**

- Hyperglycemia-induced glucosuria, osmotic diuresis & severe fluid loss.
- Fluid loss induces dehydration & electrolyte imbalance
- Metabolic acidosis induces hyperventilation

Characters of diabetic ketoacidosis

- Hyperglycemia
- Glucosuria
- Osmotic diuresis
- Polyuria
- Thirst
- Polydipsia (increased drinking).
- Dehydration
- Electrolyte imbalance
- Ketogenesis (ketonemia, ketonuria)
- Metabolic acidosis

Clinical symptoms for diabetic ketoacidosis

- Classic features of hyperglycemia (thirst, polyuria)
- Nausea, vomiting, abdominal pain
- Tachycardia
- Kussmaul–Kien respiration (rapid & deep).
- Ketotic breath (fruity, with acetone smell)
- Mental status changes (confusion, coma)

Diagnostic Criteria in diabetic ketoacidosis

- Blood glucose level > 250 mg/dl
- Arterial pH < 7.35
- Serum bicarbonate level < 15 mmol/L
- Ketonemia
- Ketonuria

Lines of treatment of diabetic ketoacidosis

Adequate correction of:

- Dehydration (Fluid therapy)
- Hyperglycemia (Insulin)
- Electrolyte deficits (Potassium therapy)
- Ketoacidosis (Bicarbonate therapy)

- Fluid therapy (Rehydration)
 - Restore blood volume and perfusion of tissues.
 - Infusion of isotonic saline (0.9% sodium chloride) at a rate of 15–20 ml/kg/hour or lactated Ringer solution..

- Insulin therapy (Short acting insulin)
 - Regular insulin, should be administered by means of continuous intravenous infusion in small doses through an infusion pump (0.1 U/kg/h).

- Insulin therapy (Short acting insulin)
 - Subcutaneous absorption of insulin is reduced in DKA because of dehydration; therefore, using intravenous routes is preferable.
 - Insulin stops lipolysis and promotes degradation of ketone bodies.

- Potassium therapy
 - potassium replacement must be initiated.
 - potassium is added to infusion fluid to correct the serum potassium concentration.

- Bicarbonate therapy
 - Correct for metabolic acidosis
 - bicarbonate therapy should be used only if the arterial pH < 7.0 after 1 hour of hydration, (sodium bicarbonate should be administered every 2 hours until the pH is at least 7.0).

Hypoglycemia

- Blood sugar of less than 70 mg/dl is considered hypoglycemia.
- Is a life threatening disorder that occurs when blood glucose level becomes < 50 mg/dl
- One of the common side effects of insulin in treating type I diabetes.

Causes of Hypoglycemia

- Overdose of insulin or oral hypoglycemic drugs (sulfonylureas - meglitinides).
- Excessive physical exercise
- Missed or delayed meal.

Causes of Hypoglycemia

 Hypoglycemia can be an early manifestation of other serious disorders (sepsis, congenital heart disease, brain hemorrhage).

Characters of Hypoglycemia

Autonomic features

- ↑ sympathetic: tachycardia, palpitation,
 sweating, anxiety, tremor.
- − ↑ parasympathetic: nausea, vomiting.

Characters of Hypoglycemia

Neurological defects:

- Headache, visual disturbance, slurred speech, dizziness.
- Tremors, mental confusion, convulsions.
- Coma due to \downarrow blood glucose to the brain.

Precautions

Hypoglycemia can be prevented by:

- Monitoring of blood glucose level (blood sugar level should be checked routinely).
- Patients should carry glucose tablets or hard candy to eat if blood sugar gets too low.

Precautions

- Diabetic patient should wear a medical ID bracelet or carry a card.
- Patient should not skip meals or eat partial meals.
- Patient should eat extra carbohydrates if he will be active than usual.

Treatment of Hypoglycemia

Conscious patient:

Sugar containing beverage or food (30 g orally).

Unconscious patient:

- Glucagon (1 mg S.C. or I.M.)
- 20-50 ml of 50% glucose solution I.V. infusion (risk of possible phlebitis).

| | Hypoglycemic coma | Hyperglycemic coma Diabetic ketoacidosis |
|------------------------|--|--|
| | (Excess insulin) | (Too little insulin) |
| Onset | Rapid | Slow - Over several days |
| Acidosis & dehydration | No | Ketoacidosis |
| B.P. | Normal | Subnormal or in shock |
| Respiration | Normal or shallow | air hunger |
| Skin | Pale & Sweating | Hot & dry |
| CNS | Tremors, mental confusion, sometimes convulsions | General depression |
| Blood sugar | Lower than 70 mg/100cc | Elevated above 200 mg/100cc |
| Ketones | Normal | Elevated |

SUMMARY

• Hyperglycemic ketoacidosis: treated by insulin, fluid therapy, potassium supplement and bicarbonate.

• Hypoglycemia: treated by oral glucose tablets, juice or honey (if the patient is conscious) and by 20-50 ml of 50% glucose solution I.V. infusion or glucagon (1 mg, S.C. or I.M.) (if the patient is unconscious).
