Physiology of pregnancy

DR. HANA ALZAMIL

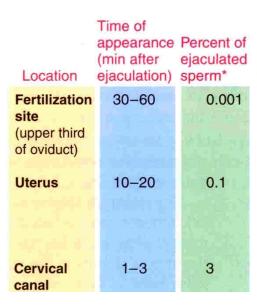

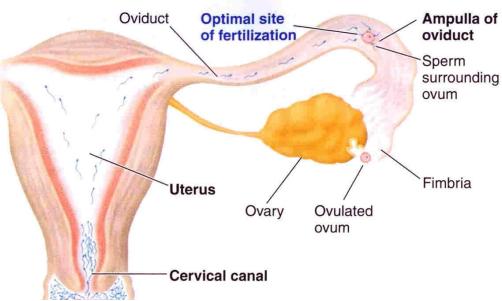

Objectives

- Describe Fertilization & implantation of the blastocyst into the endometrium.
- Recognize the development and normal physiology of the placenta
- Describe the physiological functions of placental hormones during pregnancy
- Explain the physiological responses of mother's body to pregnancy

Revision (large group activity)

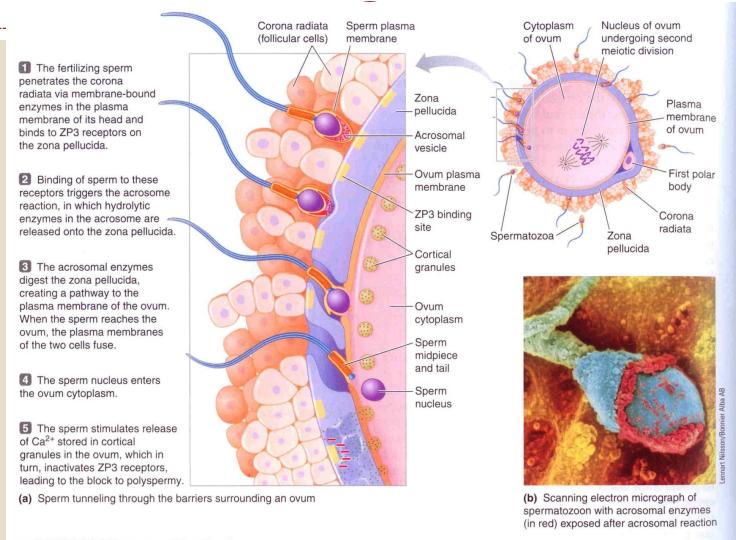

- How many sperms in the ejaculated semen?
- In which stage the ova is after ovulation?
- What is the % of ovulated ova that can reach fallopian tube?
- Can the ova released from the right ovary reaches the left fallopian tube?

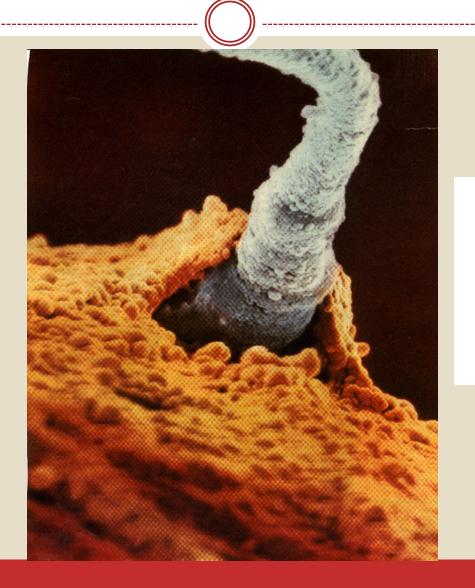

Small group activity

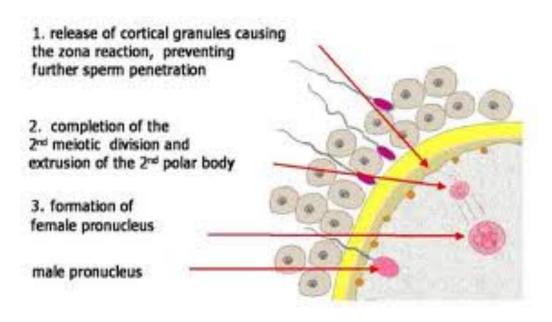

- What are the factors that help the ovulated ova to reach the fallopian tube?
- What are the factors that help the sperm to travel in the female genital tract?

• FIGURE 20-25 Process of fertilization.

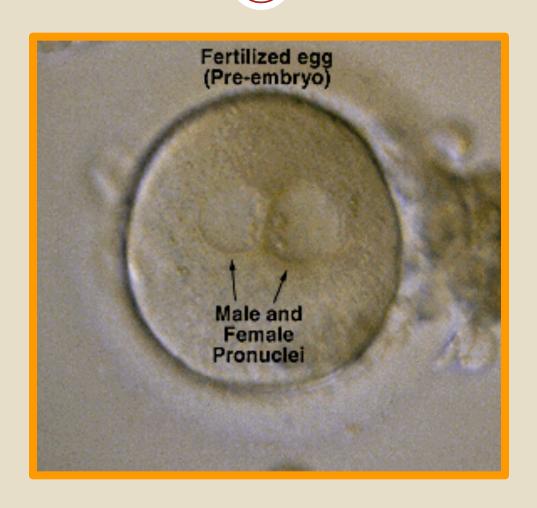

- After ejaculation sperms reach ampulla of fallopian tube within 30-60 min (ut cont)
- Sperm penetrate corona radiata and zona pellucida (hyaluronidase & proteolytic enzymes)
- Oocyte divides to form mature ovum (female pronucleus 23 unpaired chr) + 2nd polar body
- Head of sperm swells (male pronucleus 23 unpaired chr)
- Fertilized ovum (zygote) contain 23 paired chr

Zygote

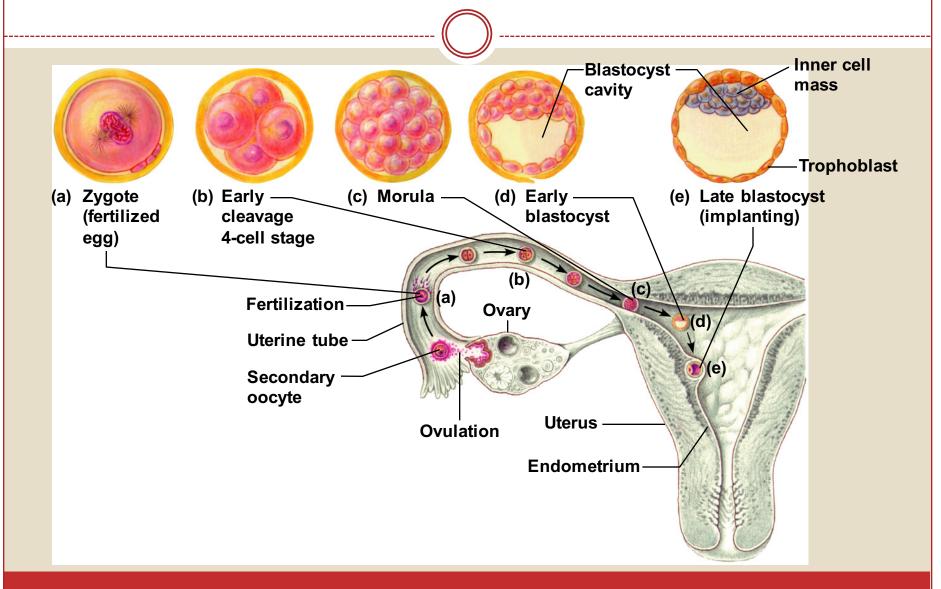

- Following fertilization the zygote undergoes several mitotic divisions inside the zona pellucida (overall size does not change).
- 1st cleavage yields a 2 celled embryo,
 - o each cell is called a blastomere and is totipotent
- Divisions continue rapidly until the 32 cell stage

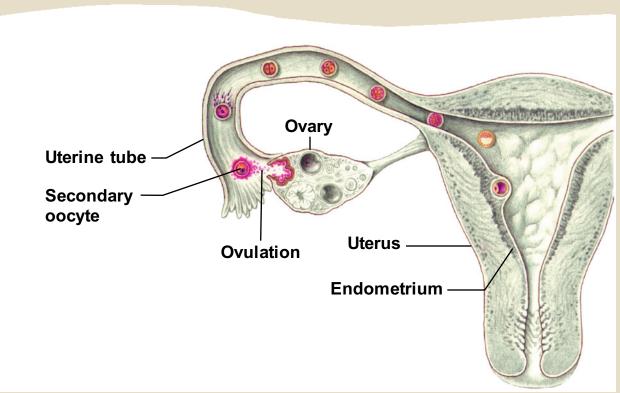

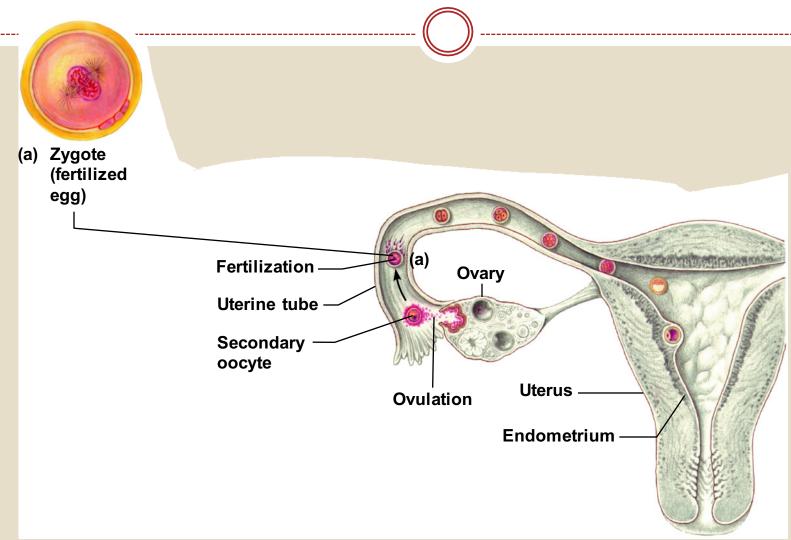

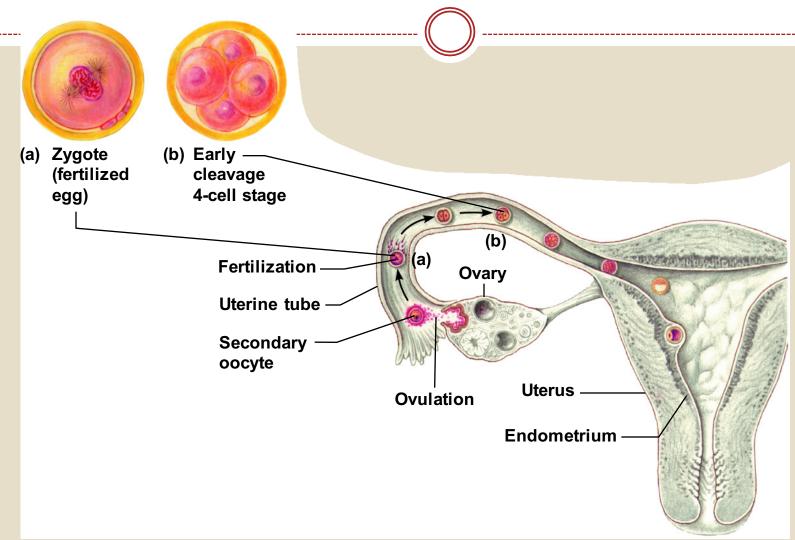

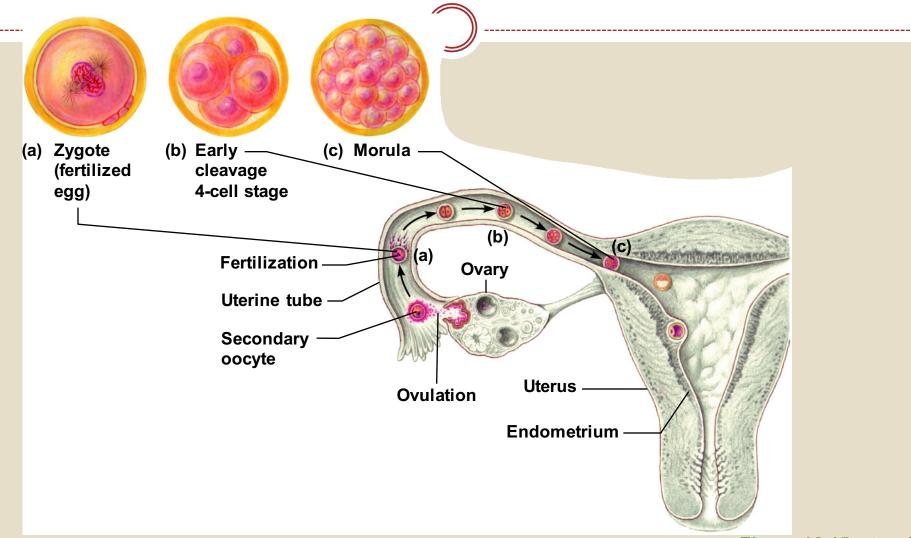

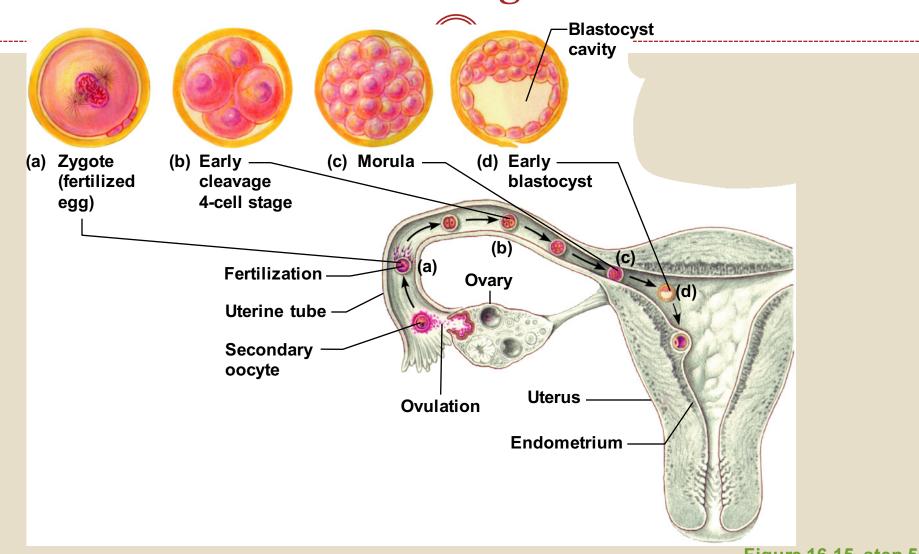

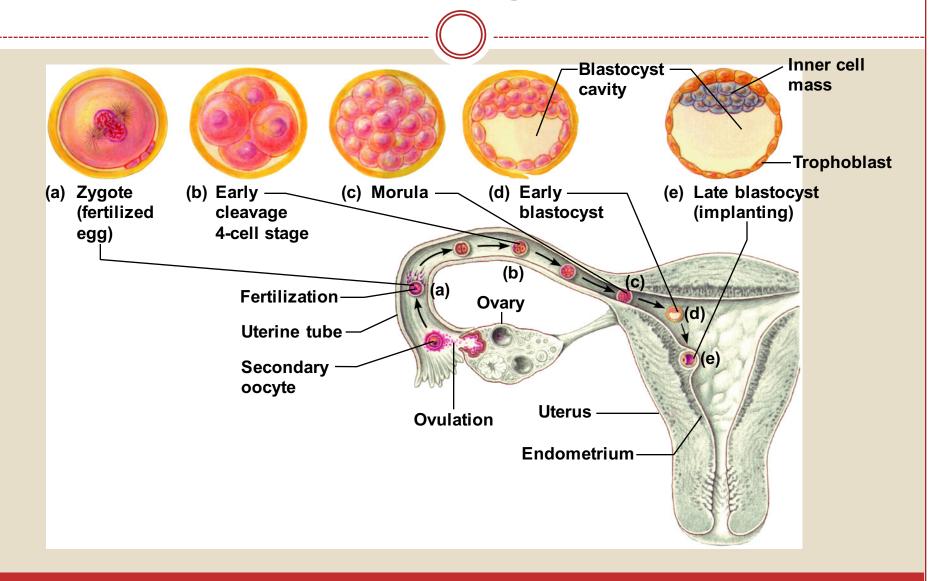

Figure 16.15, step 1

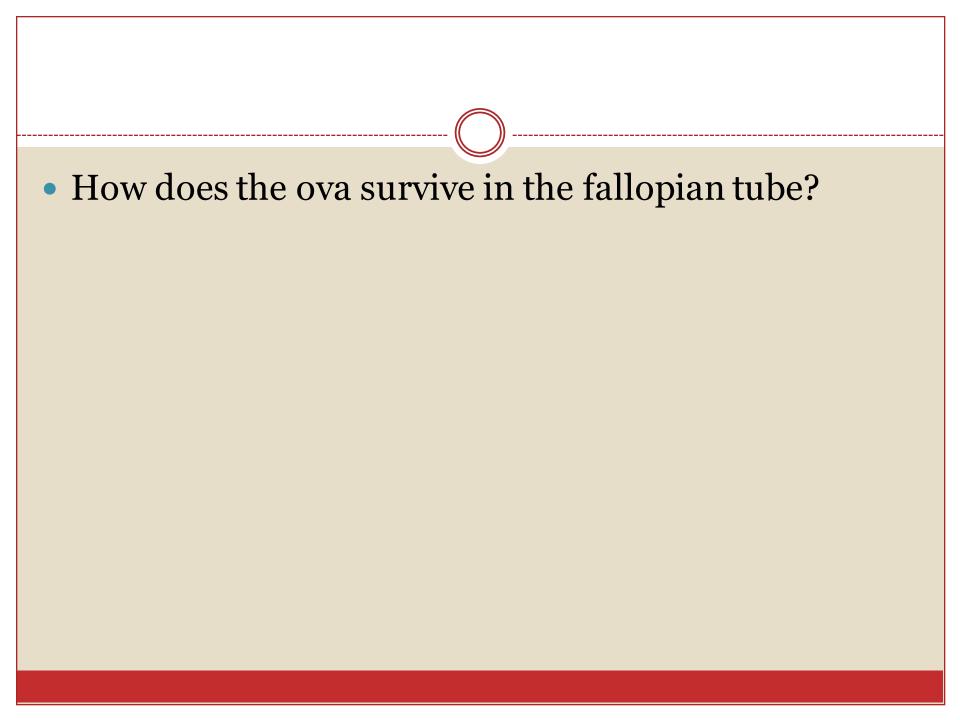

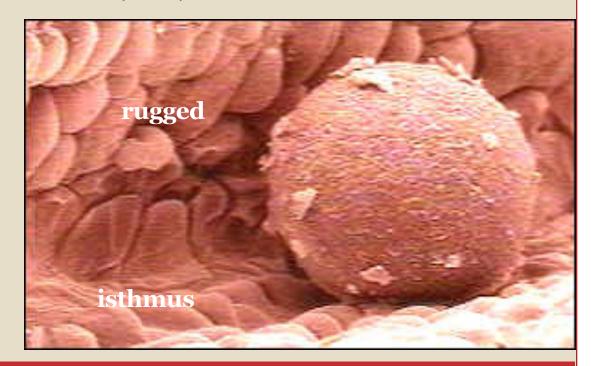

Traveling

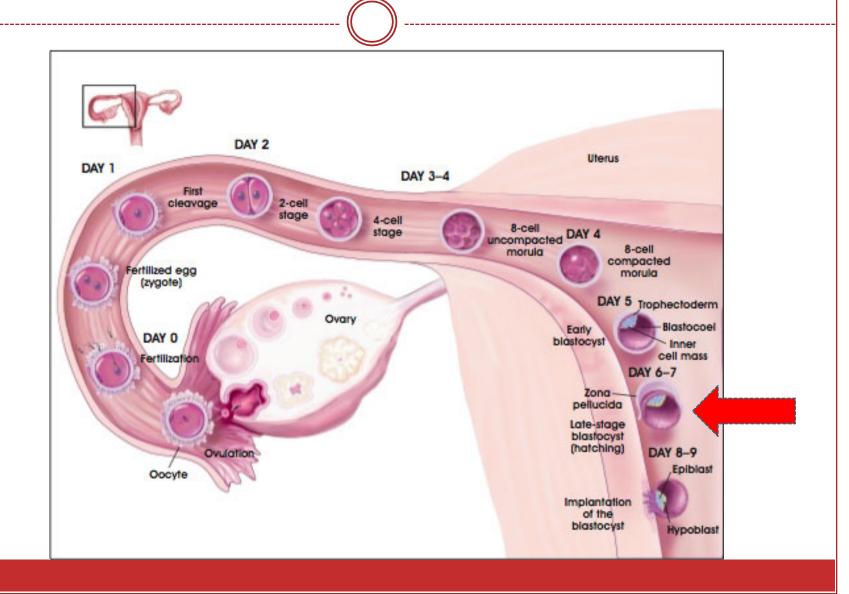

- Zygote begins to divide as it travels through oviduct
- Nutrition of blastocyst (secretory cells in fallopian tube)
- Effect of Progesterone on (SM) of isthmus

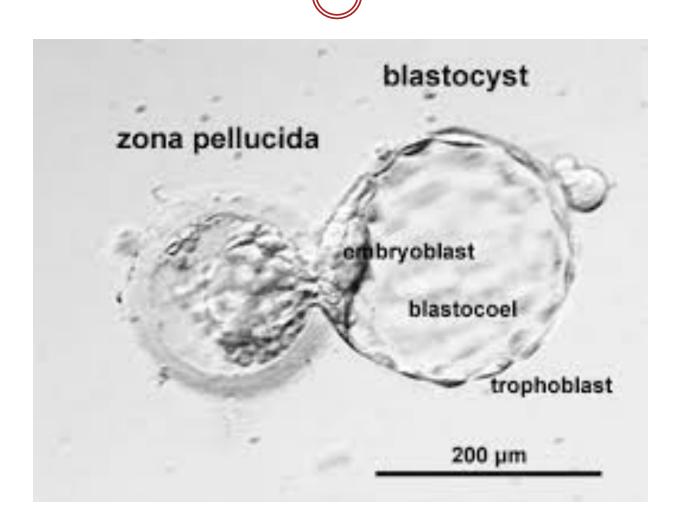

Transport of fertilized ovum

- After fertilization 3-5 days till zygote reach uterine cavity
- Transport: fluid current + action of cilia + weak contractions of the fallopian tube (estrogen, PGs)
- Isthmus (last 2cm) relaxes under effect of progesterone
- Delayed transport allows cell division
- Blastocyst (100 cells) enters the uterus

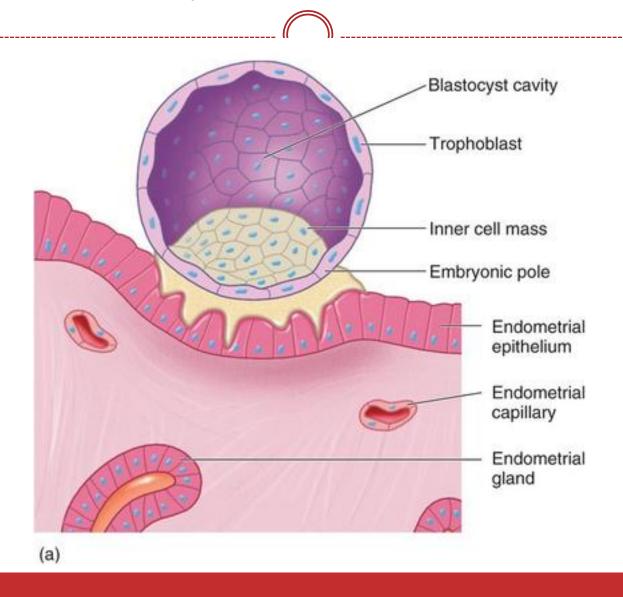

Transport of fertilized ovum

Hatching

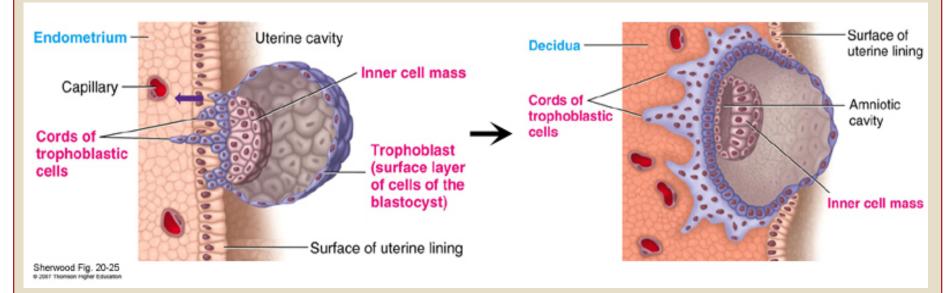

Blastocyst differentiation

Implantation

- Digestion of endometrium
- Decidual cells (glycogen, proteins, lipids & minerals)

(والله أنبتكم من الأرض نباتا)

يسمي علماء الأجنة عملية إنغراس النطفة الأمشاج المنقسمة والتي تعرف باسم الأرومة المتكيسة في جدار الرحم باسم عملية الاستنبات أو الاستزراع

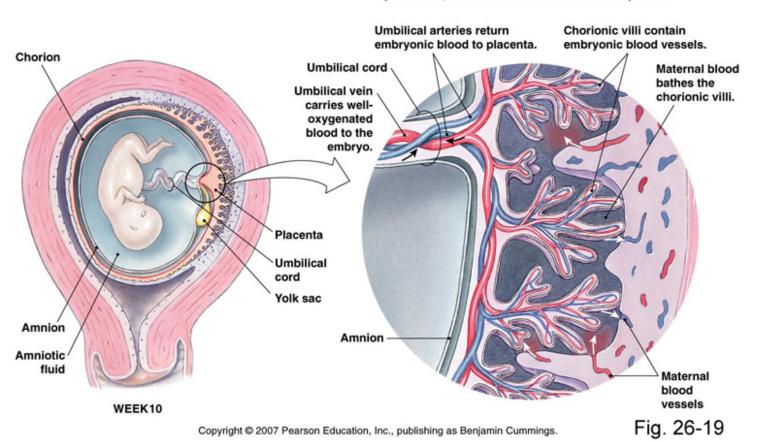

Placenta

- Trophoblastic cords from blastocyst
- Blood capillaries grow in the cords
- 21 days after fertilization blood start to be pumped by fetal heart into the capillaries
- Maternal blood sinuses develop around the trophoblastic cords
- More and more trophoblast projections develop (placental villi)

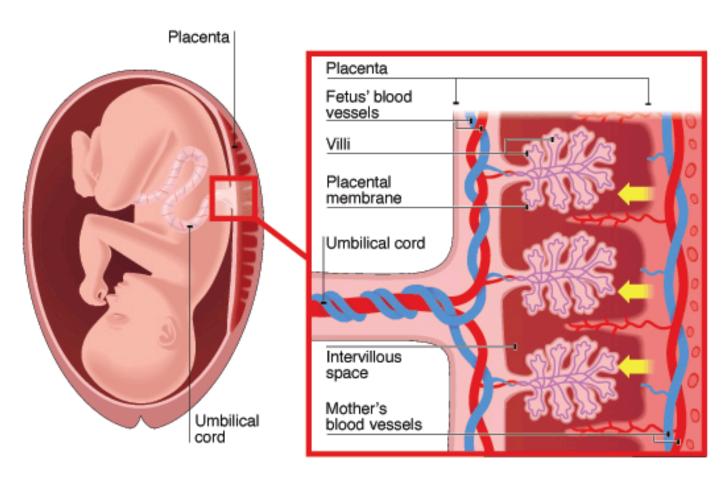

Placenta

Some material is exchanged across placental membranes by diffusion, but other material must be transported.

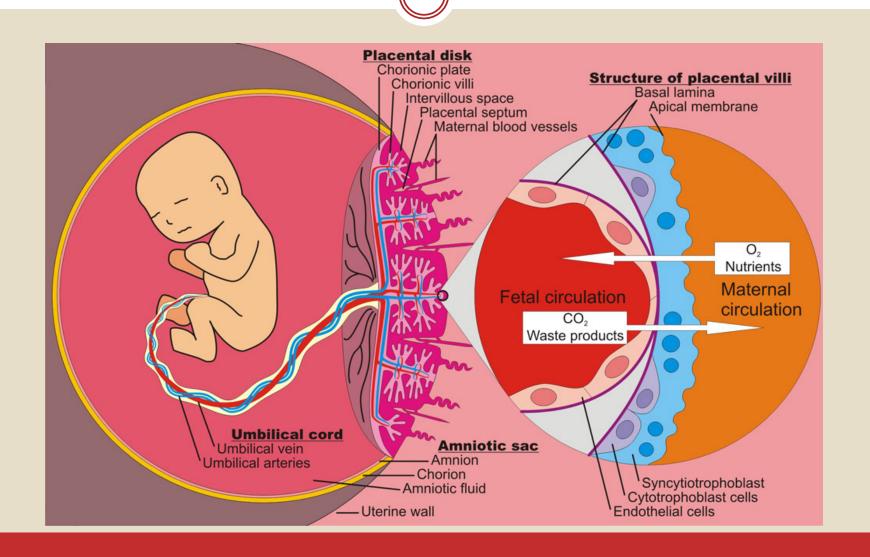

Function of the placenta

- Major function:
 - Respiration
 - Nutrition
 - Excretion
- Endocrine
- Protection

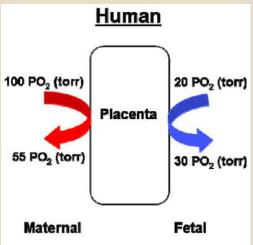

- PCO₂ 2-3 mm Hg higher in fetal than maternal blood
- Dissolved O₂ in mother's blood passes to fetal blood by simple diffusion

 $PO_2 50 \text{ mm Hg (M)} - 30 \text{ mm Hg (F)} = 20 \text{ mmHg}$

• At low PO₂HbF carry 20-50% more O₂ than HbA (HbF has a higher oxygen carrying capacity than HbA)

Human

HbF conc 50% higher than HbA in mother

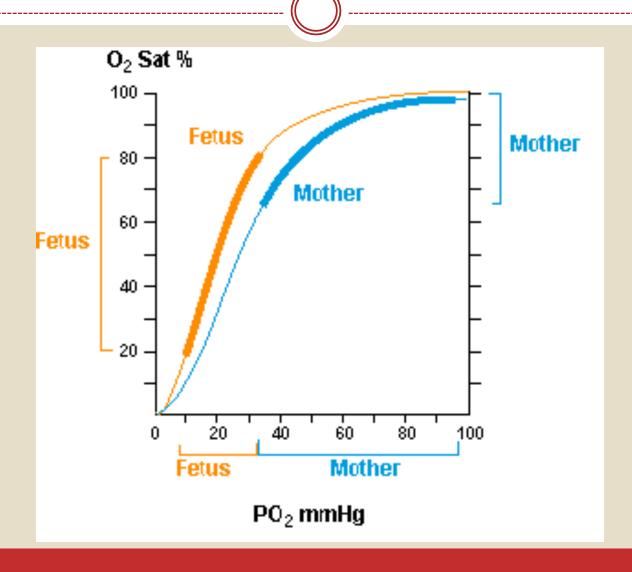

- Double Bohr effect
 - ➤ Low pH in mother's blood (acidic)
 - ➤ High pH in fetal blood (alkaline)

Important shifts of the dissociation curves take place in the placenta:

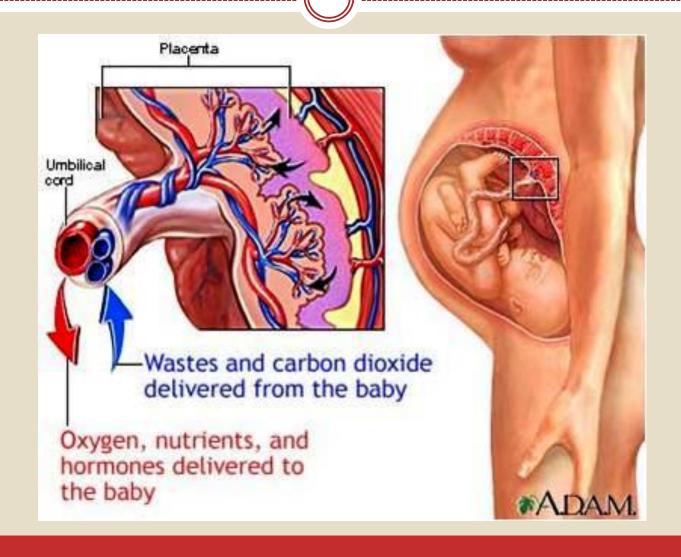

- The maternal blood gains CO₂, the pH falls and the curve shifts to the right releasing additional oxygen.
- On the fetal side of the placenta CO₂ is lost, the pH rises and the curve shifts to the left allowing additional oxygen uptake.

Oxygen dissociation curve

Important factors facilitate delivery of oxygen to the fetal tissues

- High maternal intervillous blood flow (almost double the fetal placental flow)
- High fetal haemoglobin (16 17 g/dl)
- High fetal cardiac output
- The fetal metabolic acidosis which shifts the curve to the right and thus aids delivery of oxygen to the tissues.

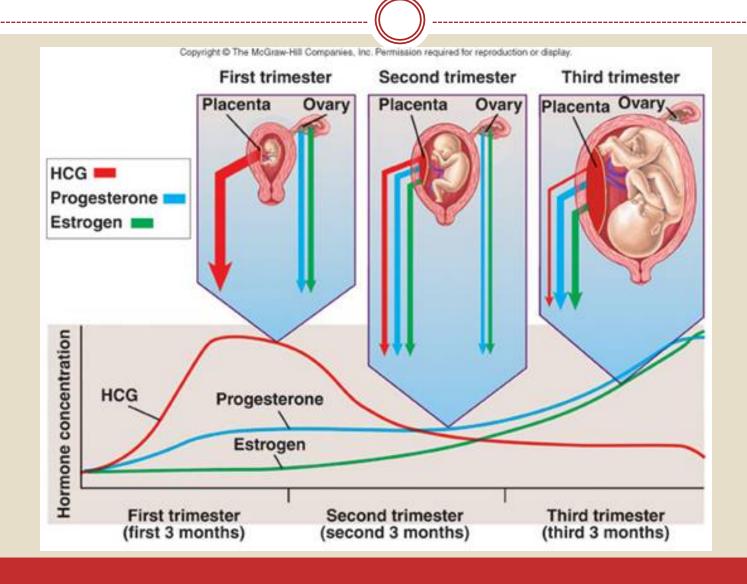

Nutrition

- Fetus uses mainly glucose for nutrition so the trophoblast cells in placental villi transport glucose by carrier molecules; GLUT (facilitated diffusion)
- Fatty acids diffuses due to high solubility in cell membrane (more slowly than glucose)
- The placenta actively transports all amino acids, with fetal concentrations exceeding maternal levels.
- K+, Na+ and Cl- diffuses from maternal to fetal blood

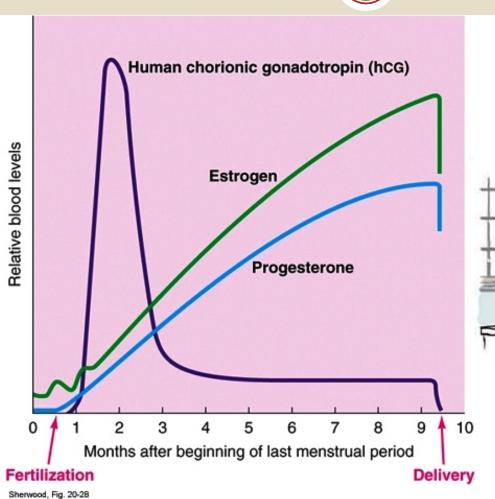

Excretion

- Excretory products of the fetus diffuse through placental membrane to maternal blood to be excreted with waste products of the mother
 - Urea, uric acid and creatinine
- Higher conc. Of excretory products in fetal blood insures continuous diffusion of these substances to the maternal blood

- Human Chorionic Gonadotropin (hCG)
 - Glycoprotein
 - Most important function is to maintain corpus luteum (↑estrogen & progesterone) till 13-17 weeks of gestation
 - Exerts interstitial (Leyding) cell-stimulating effect on testes of the male fetus (growth of male sex organs)

hCG level (pregnancy test)

"Well... I think we should run a pregnancy test. Just to make sure!"

Estrogen

- Steroid hormone
- Secreted by syncytial trophoblast cells
- Towards end of pregnancy reaches 30×
- Derived from weak androgen (DHEA) released from maternal & fetal adrenals

Functions in the mother

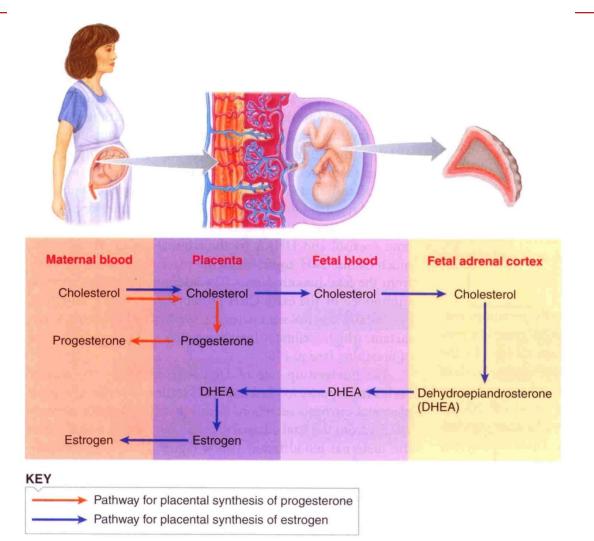

- Enlargement of uterus, breast ducts & external genitalia
- Relaxation of pelvic ligaments in preparation to labor
- Activation of the uterus (gap junctions)

Progsterone

- Steroid hormone
- Secreted by syncytial trophoblast cells
- Towards end of pregnancy reaches 10×
- Derived from cholesterol

Functions in the mother

- Development of the breast lobules.
- Provides nutrition to developing embryo
- Development of decidual cells
- Inhibit the contractility of the uterus

• FIGURE 20-31 Secretion of estrogen and progesterone by the placenta. The placenta secretes increasing quantities of progesterone and estrogen into the maternal blood after the first trimester. The placenta itself can convert cholesterol into progesterone (orange pathway) but lacks some of the enzymes necessary to convert cholesterol into estrogen. However, the placenta can convert DHEA derived from cholesterol in the fetal adrenal cortex into estrogen when DHEA reaches the placenta by means of the fetal blood (blue pathway).

- Human Chorionic Somatomamotropin
 - Protein hormone
 - Secreted by placenta around 5th gestational week
- Functions in the mother
 - Breast development (hPL)
 - Weak growth hormone's action
 - Inhibit insulin sensitivity = ↓ glucose utilization
 - Promote release of fatty acids

Relaxin

- Polypeptide
- Secreted by corpus luteum and placenta
- Functions in the mother
 - Relaxation of symphysis pubic ligament (weak)
 - Softens the cervix at delivery

Physiological adaptation to pregnancy

Changes in maternal endocrine system

- Anterior pituitary gland enlargement (50%)
 - Release of ACTH, TSH and PL increase
 - FSH and LH almost totally suppressed
- Adrenal gland
 - Increase glucocorticoids secretion (mobilize aa)
 - Increase aldosterone (retain fluid)
- Thyroid gland enlargement (50%)
 - Increase thyroxine production (hCG)
- Parathyroid gland enlargement
 - Increase PTH secretion (maintain normal Ca⁺²)

Changes in different organs

- Increase in uterine size (50 gm to 1100 gm)
- The breasts double in size
- The vagina enlarges
- Development of edema and acne
- Masculine or acromegalic features
- Weight gain 10-12 kg (last 2 trimesters)
 - Increase appetite
 - ➤ Removal of food by fetus
 - ▼ Hormonal effect

Changes in metabolism

- Increase basal metabolic rate (15%)
- Increase in daily requirements for
 - Iron
 - Phosphates
 - Calcium
 - Vitamins
 - ➤ Vitamin D (Ca⁺² absorption)

Changes in circulatory system

- Increase in COP (30-40%) by 27 weeks
- Increase in blood flow through the placenta.
- Increase in maternal blood volume (30%) due to
 - Increase aldosterone and estrogen (↑ ECF)
 - Increase activity of the bone marrow (↑ RBCs 40%)

Changes in respiration

- Increase in O₂ consumption (20%)
 - Increase BMR
 - Increase in body size
- Growing uterus presses upwards (restriction)
- Increase in RR
- Increase in minute ventilation(TV× RR) by 50%
 - Progesterone ↑sensitivity of RC to CO₂
