Biochemistry of Addison's Disease

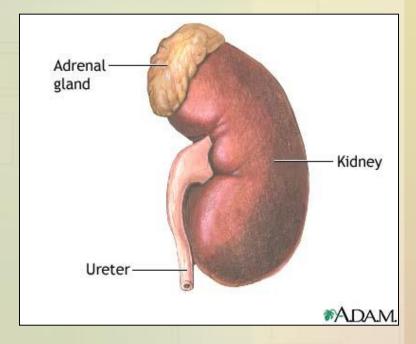

Endocrine Block

Objectives

- To identify different causes of primary adrenocortical hypofunction (Addison's disease)
- To identify secondary causes of adreno-cortical hypofunction
- To understand the diagnostic algorithm for adreno-cortical hypofunction
- To understand the interpretation of laboratory tests of adreno-cortical hypofunction

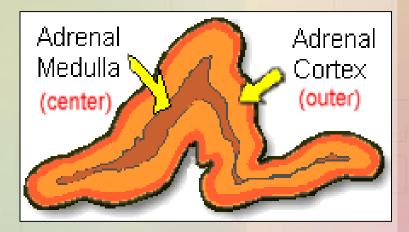

ANATOMICALLY:

 The adrenal gland is situated on the anteriosuperior aspect of the kidney

HISTOLOGICALLY:

 The adrenal gland consists of two distinct tissues of different embryological origin, the outer cortex and inner medulla.

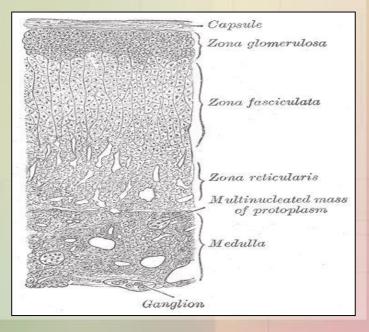

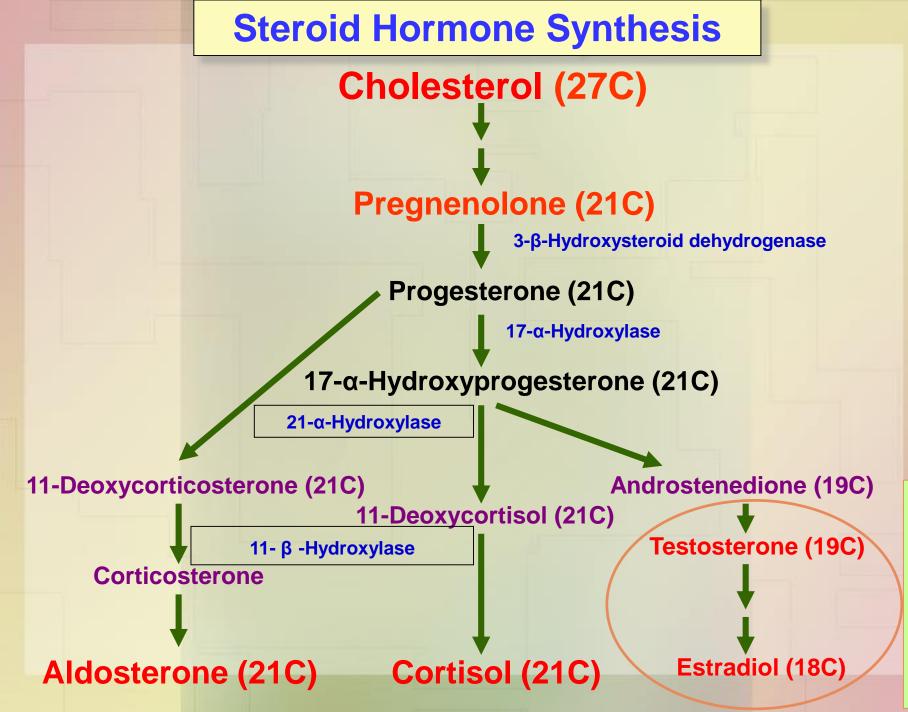

The adrenal cortex comprises three zones based on cell type and function:

➤ Zona <u>Glomerulosa</u> The outermost zone → aldosterone (the principal mineralocorticoid).

The deeper layers of the cortex:
Zona Fasciculata
→ glucocorticoids – mainly cortisol (95%)
Zona Reticularis
→ Sex hormones

Peripheral tissues

Aldosterone Hormone

 The principal physiological function of aldosterone is to conserve Na⁺, mainly by facilitating Na⁺ reabsorption and reciprocal K⁺ or H⁺ secretion in the distal renal tubule.

 aldosterone is a major regulator of water and electrolyte balance, as well as blood pressure.

- Aldosterone, by acting on the <u>distal</u> <u>convoluted tubule</u> of kidney, leads to:

 Renin-Angiotensin system is the most important regulatory mechanism for aldosterone secretion

The renin - angiotensin system

- It is the <u>most important system</u> controlling aldosterone secretion.
- It is involved in **B.P. regulation**.

Renin:

- a proteolytic enzyme produced by the juxtaglomerular cells of the afferent renal arteriole.
- Sensitive to B.P. changes through baroreceptors
- released into the circulation in response to :
 - a fall in circulating blood volume.
 - a fall in renal perfusion pressure.
 - loss of Na⁺.

Causes of adrenocortical hypofunction (AC)

A. Primary AC hypofunction (destruction of adrenal gland, Addison's disease): Autoimmune Infection, e.g., tuberculosis Infiltrative lesions, e.g., amylodosis

B. Secondary AC hypofunction: Pituitary tumors Vascular lesions Head trauma Hypothalmic diseases latrogenic (steroid therapy, surgery or radiotherapy)

Signs and symptoms of primary adrenal failure (Addison's disease)

- The symptoms are precipitated by trauma, infection or surgery:
- Lethargy, weakness, nausea & weight loss.
- Hypotension especially on standing (postural)
- Hyperpigmentation (buccal mucosa, skin creases, scars)
- Deficiency of both glucocorticoids and mineralocorticoids
- Hypoglycemia, Va+, K+ and raised urea
- Life threatening and need urgent care.

Hyperpigmentation in Addison's disease

Hyperpigmentation occurs because <u>melanocyte</u>stimulating hormone (MSH) and (ACTH) share the same precursor molecule, <u>Pro-</u>opiomelanocortin (POMC).

- The anterior pituitary POMC is cleaved into ACTH, γ -MSH, and β -lipotropin.
- The subunit ACTH undergoes further cleavage to produce α-MSH, the most important MSH for skin pigmentation.
- In secondary adrenocortical insufficiency, skin darkening does not occur.

Investigation of Addison's disease (AD)

- The patient should be hospitalized
- Basal measurement of: Serum urea, Na⁺, K⁺ & glucose Serum cortisol and plasma ACTH
- Definitive diagnosis and confirmatory tests should be done later after crisis.

Investigation of Addison's disease (AD) Cont'd

- Normal serum cortisol and UFC does not exclude AD.
- Simultaneous measurement of cortisol and ACTH improves the accuracy of diagnosis of primary adrenal failure: Low serum cortisol (<200nmol/L) and High plasma ACTH (>200 ng/L)

Confirmatory Tests

- 1. Short tetracosactrin (Synacthen) test (Short ACTH stimulation test)
- Measure basal S. cortisol
- Stimulate with I.M. synthetic ACTH (0.25 mg)
- Measure S. cortisol 30 min after I/M injection
- Normal: 1 of S. cortisol to >500 nmol/L
- Failure of S. cortisol to respond to stimulation, confirm AD.
- Abnormal results:
 - emotional stress
 - glucocorticoid therapy
 - estrogen contraceptives.

Confirmatory Tests

Cont'd

2. Adrenal antibodies

- Detection of adrenal antibodies in serum of patients with autoimmune Addison's disease
- 3. Imaging (Ultrasound/CT)
- Ultrasound or CT for adrenal glands for identifying the cause of primary adrenal failure

Investigation of Secondary AC Insufficiency

- Low serum cortisol with low plasma ACTH
- No response to short synacthen test: Adrenocortical cells fail to respond to short ACTH stimulation
- Depot Synacthen test (confirmatory test)
 - 1. Measure basal S. cortisol
 - 2. Stimulate with I.M. synthetic ACTH (1.0 mg) on each of three consecutive days
 - 3. Measure S. cortisol at 5 hours after I.M. injection on each of the three days

Investigation of Secondary AC Insufficiency Depot Synacthen test Cont'd Interpretation of results:

- Addison's disease: No rise of S. cortisol >600 nmol/L at 5 h after 3rd injection.
- Secondary AC: Stepwise increase in the S. cortisol after successive injections
- Limitations:

Hypothyroidism: Thyroid deficiency must be corrected before testing of adrenocortical functions

Prolonged steroid therapy

Investigation of Secondary AC Insufficiency Cont'd Other Investigations

 Insulin-induced hypoglycemia: Adrenal failure secondary to pituitary causes

MRI for pituitary gland

Investigation for Addison's disease

- Basal plasma ACTH and basal serum cortisol, glucose, urea and electrolytes
- Screening
- High ACTH and Low cortisol

- Short ACTH stimulation test: No response
- Confirmation

- Adrenal autoantibodies
- Ultrasound/CT adrenal glands
- Others
