Gastro-esophageal reflux disease

OBJECTIVES

- Describe the following aspects of reflux esophagitis:
 - 1) Definition
 - 2) Pathogenesis
 - 3) Clinical features
 - 4) Pathology (gross and microscopic features)
 - 5) Complications
- Describe the following aspects of Barrett esophagus:
 - 1) Definition
 - 2) Main cause
 - 3) Pathology (gross and microscopic features)
 - 4) Complications (dysplasia and adenocarcinoma)

Definition

- American College of Gastroenterology (ACG)
 - Symptoms OR mucosal damage produced by the abnormal reflux of gastric contents into the esophagus
 - Often chronic and relapsing
 - May see complications of GERI in patients who lack typical symptoms

Reflux Esophagitis Gastroesophageal Reflux Disease (GERD)

- Gastroesophageal reflux is a normal physiologic phenomenon experienced intermittently by most people, particularly after a meal.
- Gastroesophageal reflux disease (GERD)
 occurs when the amount of gastric juice
 that refluxes into the esophagus exceeds
 the normal limit, causing symptoms with
 or without associated esophageal mucosal
 injury.

Physiologic vs Pathologic

- Physiologic GERD
 - Postprandial
 - Short lived
 - Asymptomatic
 - No nocturnal symptomes

- Pathologic
 GERD
 - Symptoms
 - Mucosal injury
 - Nocturnal symptomes

- Esophagitis is rarely caused by agents other than reflux
- Acute esophagitis may be caused by:

Infective agents:

- Bacterial infection is very rare, but fungal infection (mainly by Candida albicans) is common
- Viral infections of the esophagus (particularly by herpes simplex and cytomegalovirus) are seen in AIDS patient

or

Physical agents: irradiation and by ingestion of caustic agent

Epidemiology of GERD

- About 44% of the US adult population have heartburn at least once a month
- 14% of Americans have symptoms weekly
- 7% have symptoms daily

Epidemiology of GERD

 Approximately 80% of pregnant women have GERD.

 Hiatal hernia present in ~70% of people with GERD.

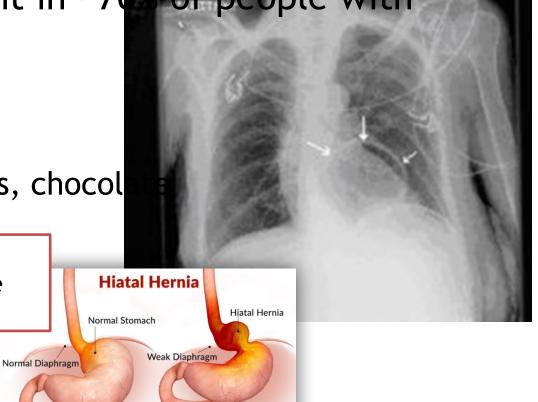

Risk factors

Smoking, alcohol

Caffeine, fatty foods, chocol

O Pregnancy obesity

Hiatal hernia: Herniation of a portion of the stomach into the lower thorax

GERD Pathophysiology

Abnormal lower esophageal sphincter

or

Increase abdominal pressure

GERD Pathophysiology

- A. Abnormal lower esophageal sphincter
- 1. Functional (frequent transient LES relaxation)
- 2. Mechanical (hypotensive LES)
- 3. Foods (eg, coffee, alcohol, smoking)
- 4. Medications (eg, calcium channel blockers),
- 5. Location <u>hiatal hernia</u>

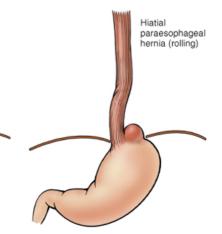

The most common cause of (GERD).

decrease the pressure of the LES.

• or

B. <u>Increase abdominal pressure</u>

Obesity
Pregnancy
Increased gastric volume

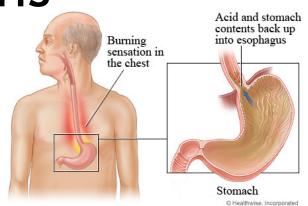

Hiatal hernia (sliding)

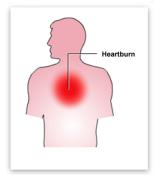

Clinical Manisfestations

- Most common symptoms
 - Heartburn—retrosternal burning discomfort and chest pain
 - Regurgitation—effortless return of gastric contents into the pharynx without nausea, retching, or abdominal contractions

Atypical symptoms....coughing (nocturnal) and wheezing (asthma).

Age: older than 40 years but also occurs in infants and children.

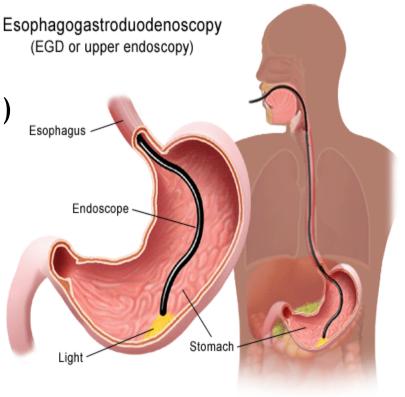

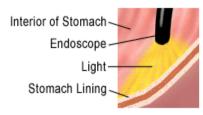

Diagnostic Evaluation

 If classic symptoms of heartburn and regurgitation exist, the diagnosis of GERD can be made clinically and treatment can be initiated

Esophagogastrodudenoscopy

- Endoscopy (with biopsy if needed)
 - In patients with unusual signs/ symptoms
 - Those who fail a medication trial
 - Those who require long-term treatment

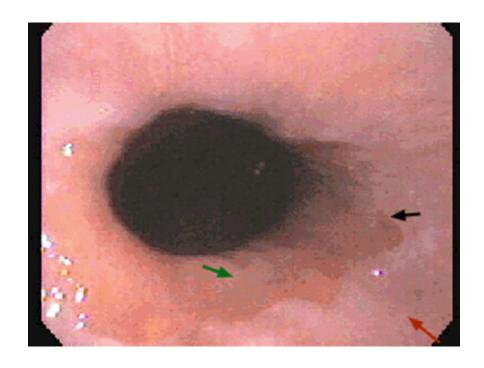

рН

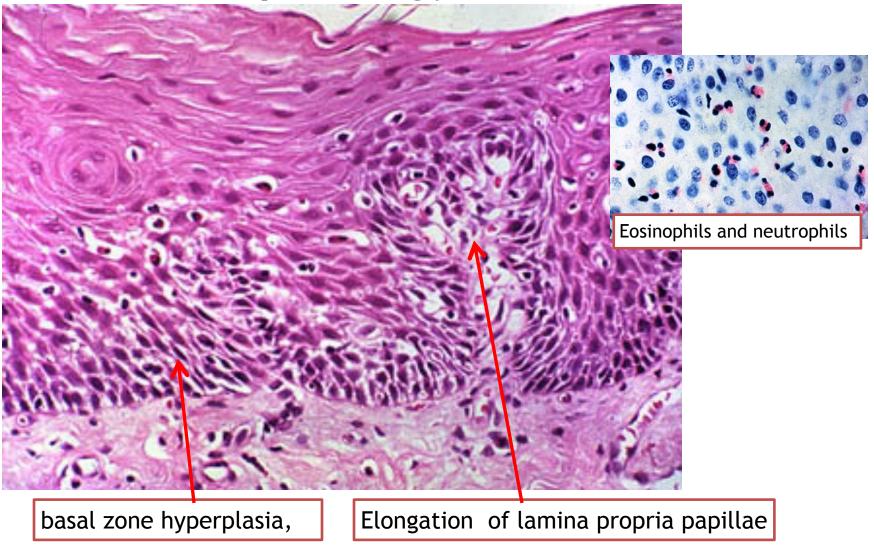

- 24-hour pH monitoring
 - Accepted standard for establishing or excluding presence of GERD for those patients who do not have mucosal changes
 - Trans-nasal catheter or a wireless capsule shaped device

Morphology

Simple hyperemia: redness

Morphology of GERD

- Changes increase with disease duration

Treatment

- H 2 receptor Blockers
- Proton pump inhibitors

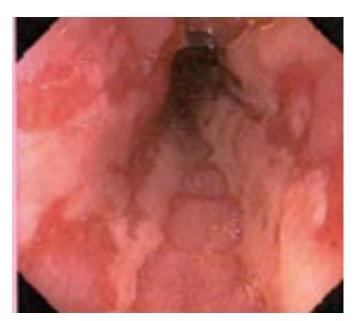

Antireflux surgery

Complications

- Erosive esophagitis and ulceration
- Hematemesis
- Melena
- Stricture
- Barrett's esophagus

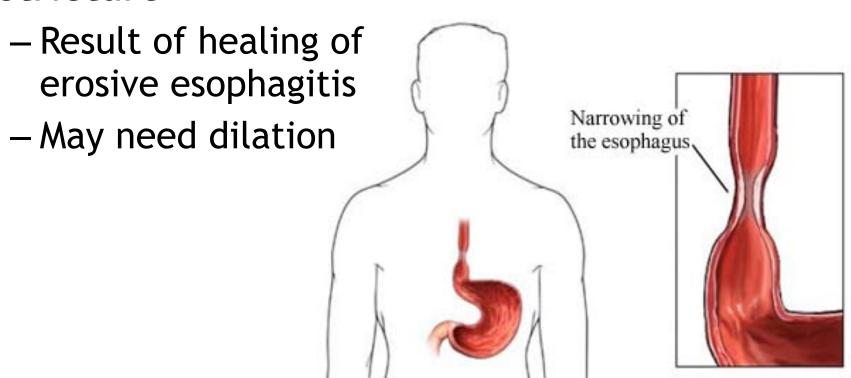

Complications

- Erosive esophagitis
 - Responsible for 40-60% of GERD symptoms
 - Severity of symptoms often fail to match severity of erosive esophagitis
 - Red mucosa with erosions and ulceration in sever cases with hematemesis and melena

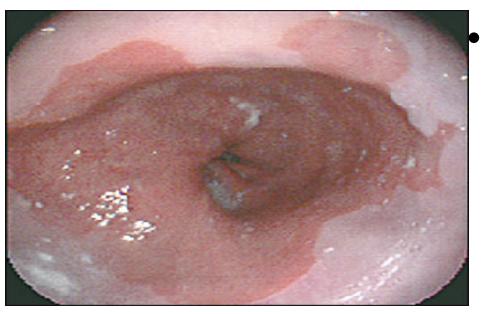

Complications

 Esophageal stricture

Complications

- Barrett's Esophagus
 - **Definition:**
 - Intestinal metaplasia of the esophagus

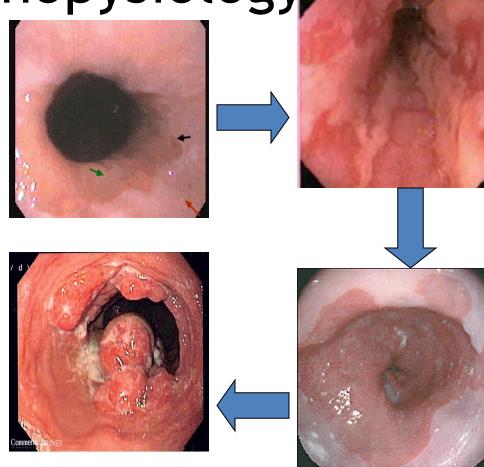

is a complication of chronic GERD that is characterized by intestinal metaplasia within the esophageal squamous mucosa

- The incidence of Barrett esophagus is rising
- Occur in 10% of individuals with symptomatic GERD
- Most common in white males and typically presents between 40 and 60 years
- Barrett esophagus can only be identified thorough endoscopy and biopsy, due to GERD symptoms

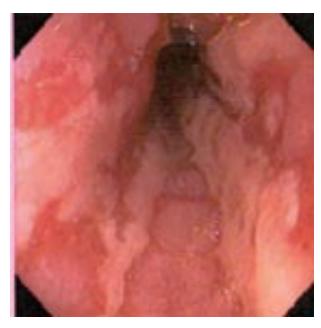

Main cause (Pathopysiology)

- Acid damages lining of esophagus and causes chronic esophagitis
- Damaged area heals in a metaplastic process and abnormal columnar cells replace squamous cells
- Associated with the development of dysplasia and adenocarcinoma (Barrett esophagus is a precursor lesion to cancer)

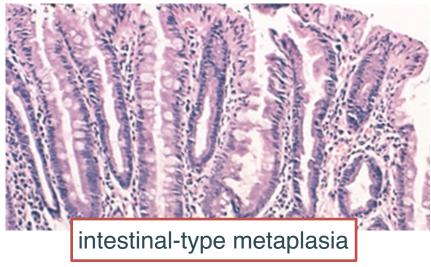

The presence of dysplasia, a preinvasive change, is associated with prolonged symptoms, longer segment length, increased patient age, and Caucasian race.

Morphology

 Endoscopic image of Barrett's esophagus: An area of red mucosa

 Barrett's esophagus is marked by the presence of columnar epithelia with goblet cells in the lower esophagus, replacing the normal squamous epithelium

Summary

Complications: Dysplasia and

 The most common malignant tumors of the esophagus are squamous carcinomas and adenocarcinomas

The prognosis for both types of carcinoma is poor

Adenocarcinoma

- Most esophageal adenocarcinomas arise from Barrett esophagus
- Other risk factors: tobacco use and exposure to radiation.
- The risk is reduced by diets rich in fresh fruits and vegetables
- Morphology: Occurs in the distal third of the esophagus and may invade the adjacent gastric cardia
- Microscopically: well to poorly differentiated adenocarcinoma
- Present with pain or difficulty in swallowing, progressive weight loss, hematemesis, chest pain, or vomiting
- Prognosis depends on the stage

Esophageal squamous cell carcinoma

- Most common in the middle and lower esophagus.
- They mostly develop in men who are heavy alcohol drinkers or heavy smokers, and may be preceded by epithelial dysplastic change.
- Not related to GERD

Case scenario: A man with retrosternal pain

- A 57-year-old presents with a history of a retrosternal burning sensation, particularly after large meals, and often on retiring to bed at night. Treatment with antacids has had little effect and he has been referred by his GP for endoscopy.
- Upper gastrointestinal tract endoscopy reveals reddening of the lower esophageal mucosa from the level of the gastroesophageal junction to a point 32 cm from the incisors. There is no evidence of a hiatus hernia. The proximal border of the reddened area is irregular, and this area is biopsied. The biopsy shows gastric and intestinal-type glandular mucosa.

1. What is the likely cause of the symptoms?

- The symptoms of 'heartburn' are suggestive of gastroesophageal reflux disease (GERD), with or without the presence of a hiatus hernia.
- Other important causes of retrosternal pain should not be overlooked, including cardiovascular causes, especially myocardial ischaemia, as well as other rarer causes including pneumothorax and musculoskeletal pain.

2. What is the final diagnosis?

 The endoscopic and biopsy appearances confirm a Barrett's oesophagus. This is a metaplastic process which develops as a result of persistent reflux of gastric contents into the esophagus, the normal squamous mucosa being replaced by glandular mucosa of gastric or intestinal type

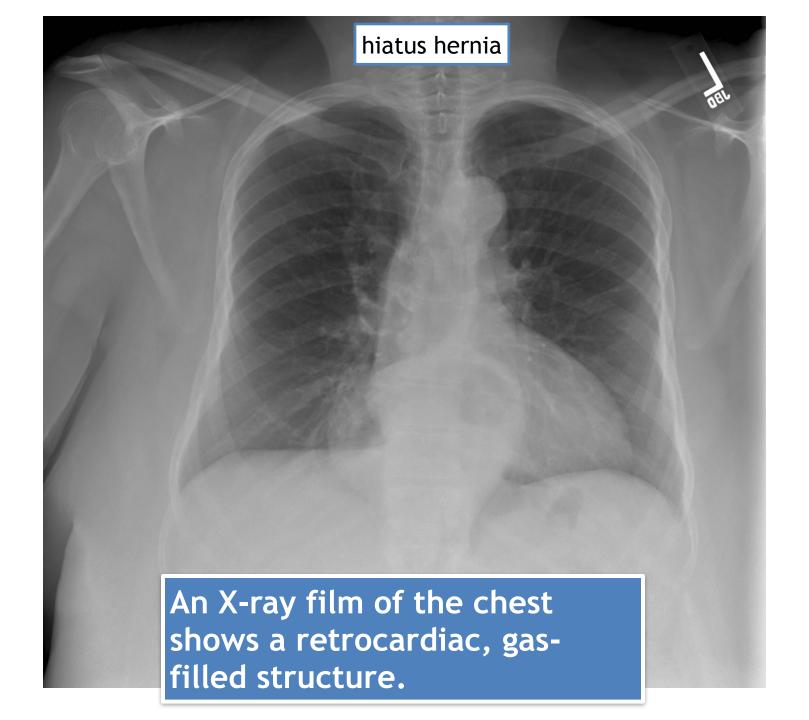

3. What further information do you require from the biopsy report?

It is important to look for dysplastic change in the biopsy which may herald the development of adenocarcinoma.

4. What are the major causes of reflux esophagitis?

- Reflux of gastric contents is the major cause of reflux esophagitis. Many factors play a role:
 - (a) the presence of a sliding hiatal hernia is the most common
 - (b) heavy alcohol use
- (c) heavy tobacco use
- (d) increased gastric volume
- (e) decreased efficacy of LES
- (f) pregnancy
- (g) CNS depressants
- (h) hypothyroidism

X ray of the chest and abdomen with contrast was done which showed marked distention and distortion of the stomach with herniation of a portion of the stomach into the lower thorax, representing hernia through the esophageal hiatus hernia

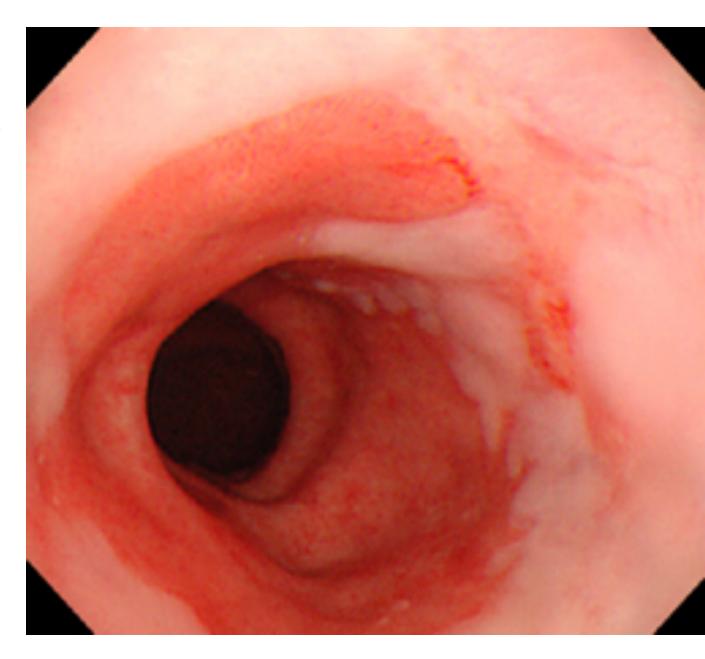

5. What are other causes of esophagitis? Ingestion of irritants (eg, alcohol, corrosive acids); infections in immunosuppressed hosts by fungi (eg, Candida) or viruses (eg, CMV, herpes); uremia; radiation therapy; graft-versushost disease; and cytotoxic anticancer therapy.

6. What are the gross and microscopic features of reflux esophagitis?

Gross featurs:

- Simple **hyperemia**
- Erosion
- Ulceration
- Stricture
- Development of Barrett esophagus
- Development of mass:

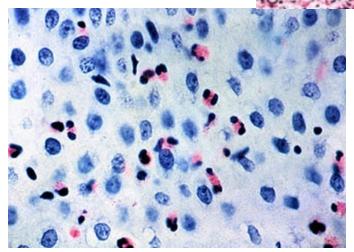

adenocarcinoma

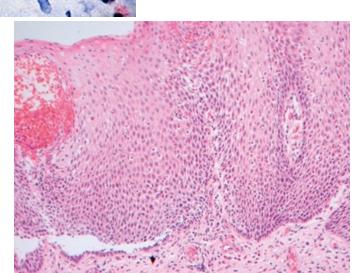

Microscopic features of reflux esophagitis

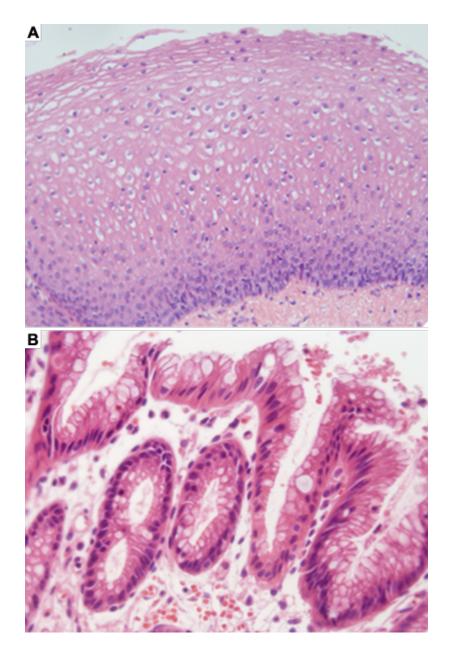

1. basal zone hyperplasia,

2. Eosinophils and neutrophils

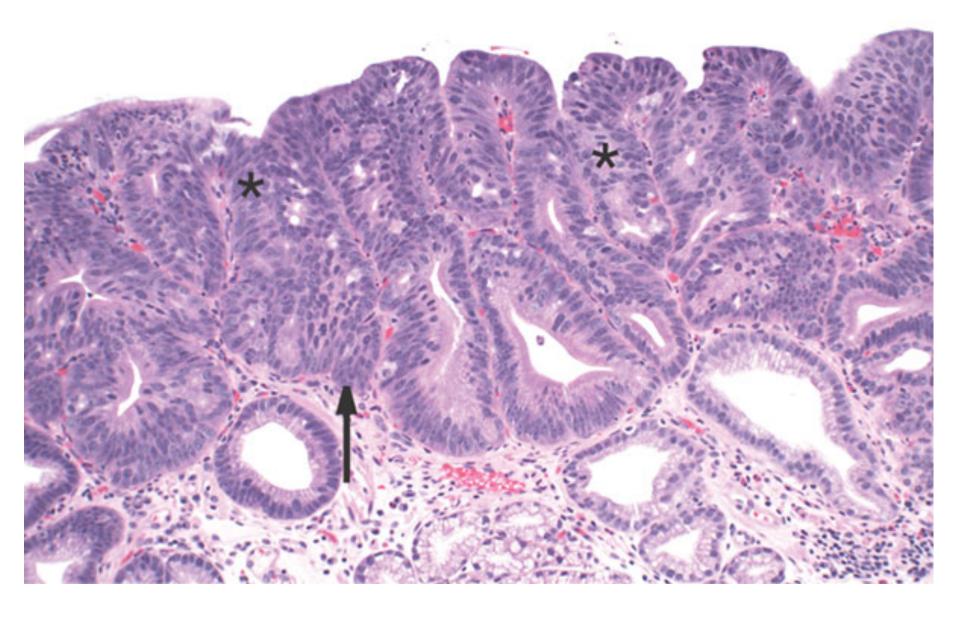

3. Elongation of lamina propria papillae

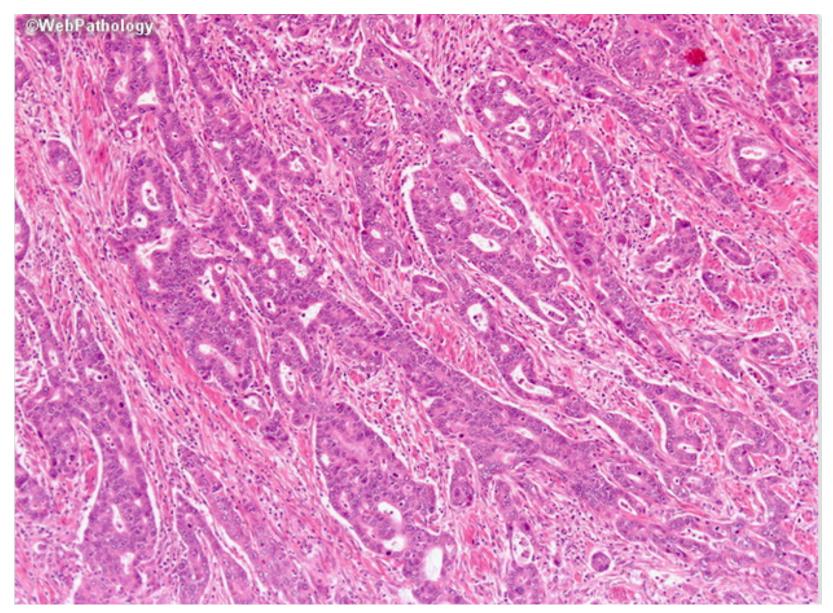

Barrett esophagus without dysplasia

Barrett esophagus with dysplasia

Adenocarcinoma in Barrett Esophagus

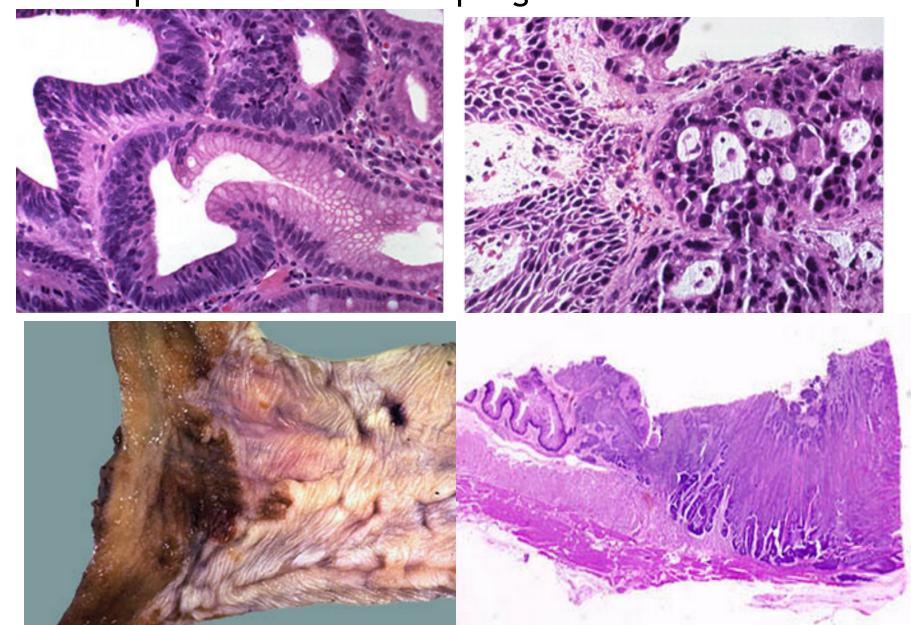

7. What are the major complications of reflux esophagitis?

The potential complications of severe reflux esophagitis are (a) ulcer; (b) bleeding; (c) development of stricture; (d) development of Barrett esophagus and adenocarcinoma.

complications of reflux esophagitis
