

**DEVELOPMENT**  
**OF**  
**PANCREAS**  
**AND**  
**SMALL INTESTINE**

**DR. SANAA AL-SHAARAWY    DR. ESSAM ELDIN SALAMA**

# **OBJECTIVES**

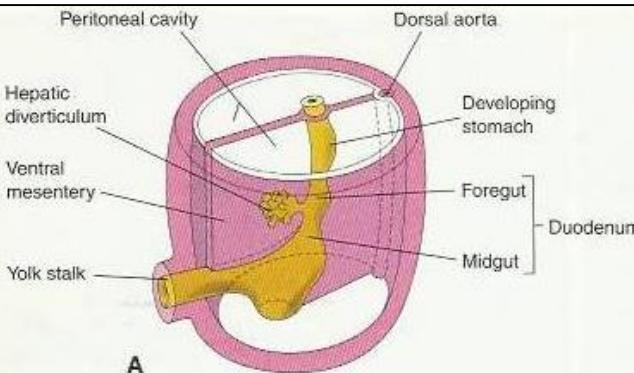

- At the end of the lecture, the students should be able to :
- Describe the development of the duodenum.
- Describe the development of the pancreas.
- Describe the development of the small intestine.
- Identify the congenital anomalies of the small intestine :
- **Congenital omphalocele.**
- **Umbilical hernia.**
- **Meckel's diverticulum.**

# DEVELOPMENT OF THE DUODENUM

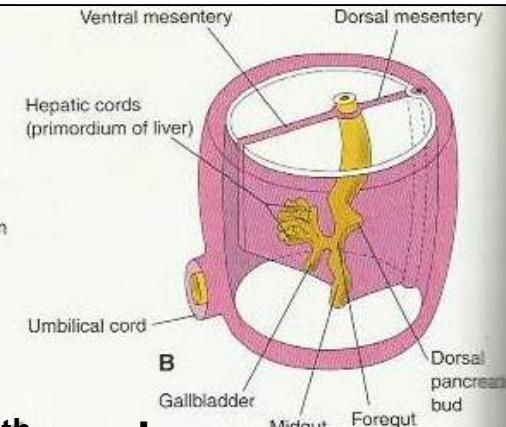

- **Stages in the development of duodenum, liver, biliary ducts and pancreas (A-D).**
- **Early in the 4<sup>th</sup> week, the duodenum develops from the endoderm of primordial gut of :**
  - **Caudal part of foregut.**
  - **Cranial part of midgut & from :**
    - **Splanchnic mesoderm.**
- The junction of the 2 parts of the gut lies just below or distal to the origin of bile duct (C &D).

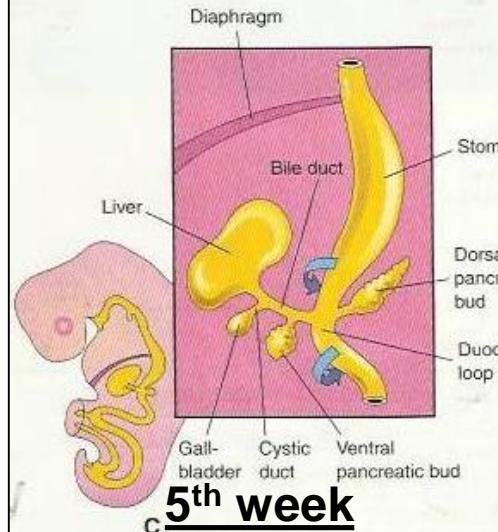

# DEVELOPMENT OF THE DUODENUM

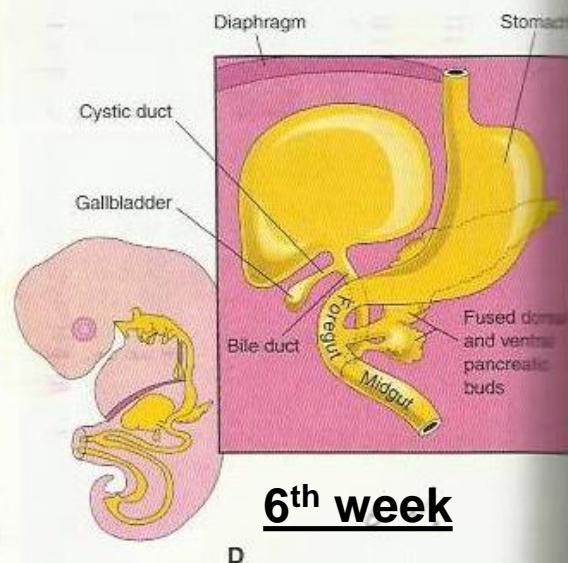

4<sup>th</sup> week

5<sup>th</sup> week

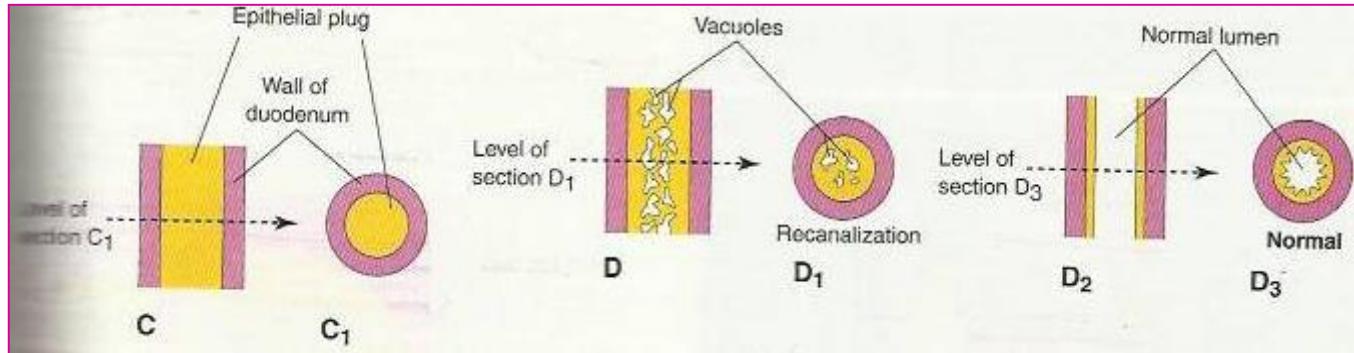

C 5<sup>th</sup> week

D 6<sup>th</sup> week

- **The duodenal loop** is formed and projected ventrally, forming **a C-shaped loop (C)**.
- **The duodenal loop** is rotated with the stomach to the right and comes to lie on the posterior abdominal wall retroperitoneally with the developing pancreas.

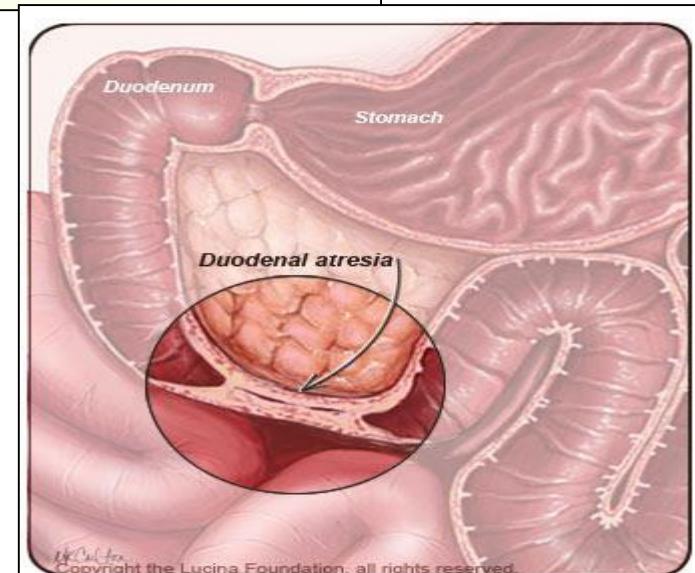

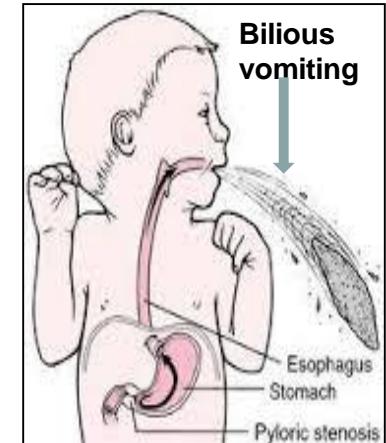

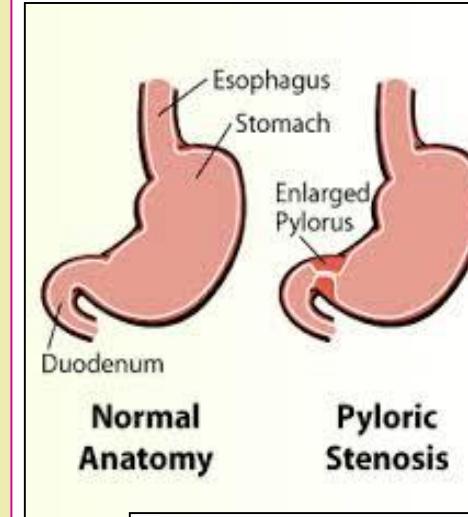

# DEVELOPMENT OF THE DUODENUM

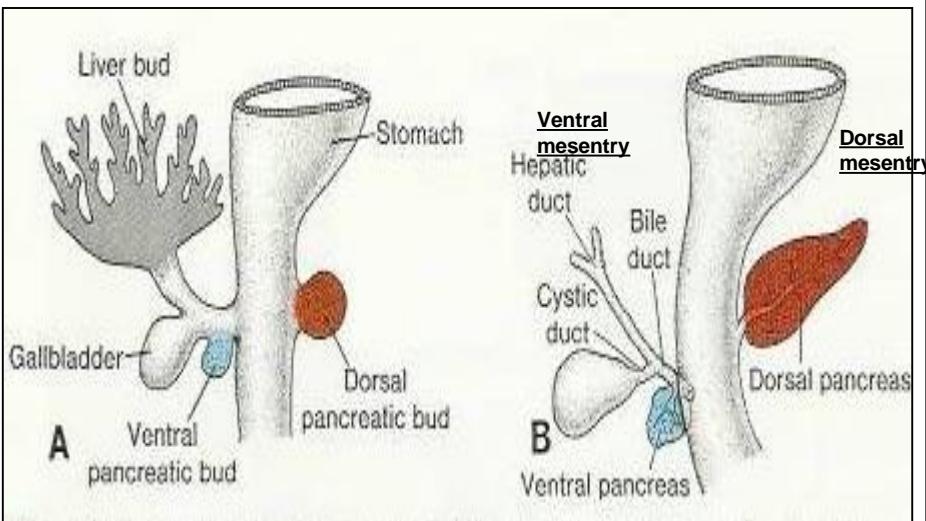

- During 5<sup>th</sup> & 6<sup>th</sup> weeks, the lumen of the duodenum is **temporarily obliterated** because of proliferation of its epithelial cells.
- Normally degeneration of epithelial cells occurs, so the duodenum normally becomes **recanalized** by the end of the embryonic period.

# Congenital anomalies

- **Duodenal stenosis**; results from incomplete recanalization of duodenum.
- **Duodenal atresia**; results from failure of recanalization leading to complete occlusion of the duodenal lumen, (autosomal recessive inheritance ).

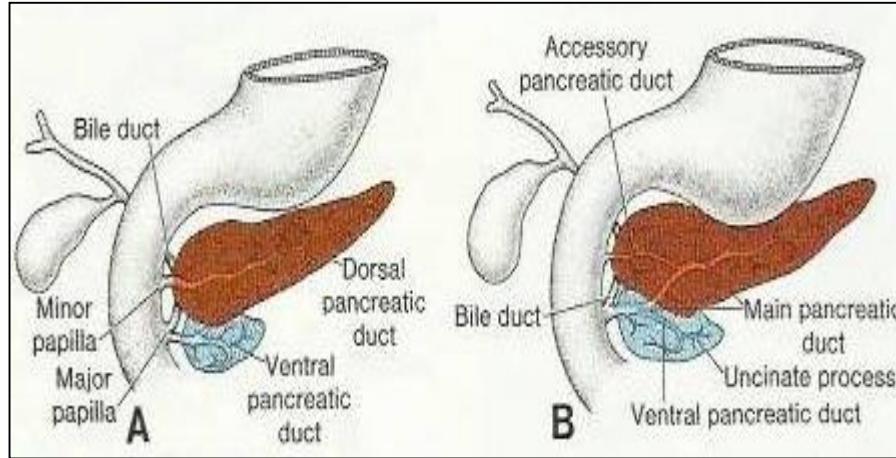

# DEVELOPMENT OF PANCREAS

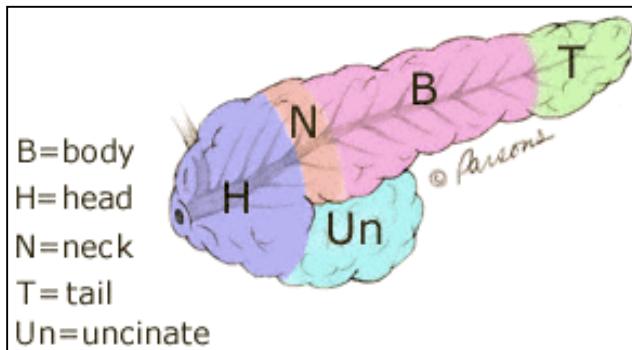

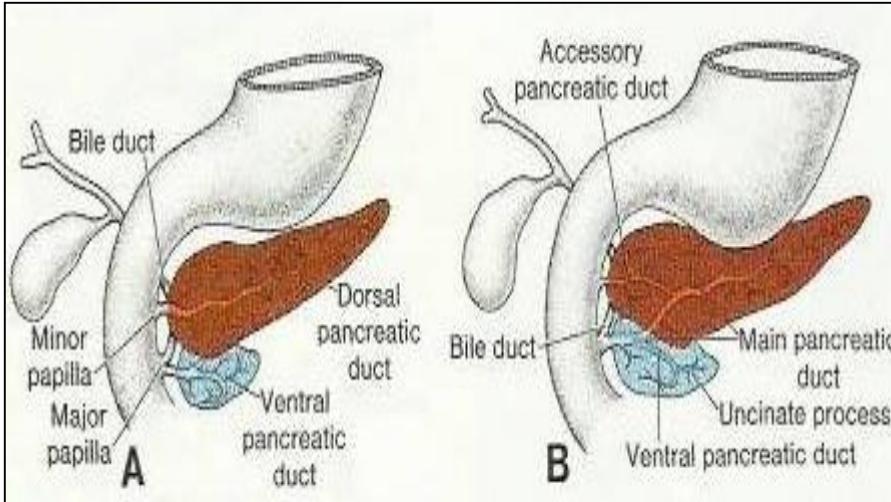

- The pancreas develops from 2 buds arising from the **endoderm** of the caudal part of foregut:
- **A ventral pancreatic bud :** which develops from the proximal end of hepatic diverticulum (forms the liver & gall bladder).
- **A dorsal pancreatic bud :** which develops from dorsal wall of duodenum slightly cranial to the ventral bud.
- **Most of pancreas** is derived from the dorsal pancreatic bud.

# DEVELOPMENT OF PANCREAS

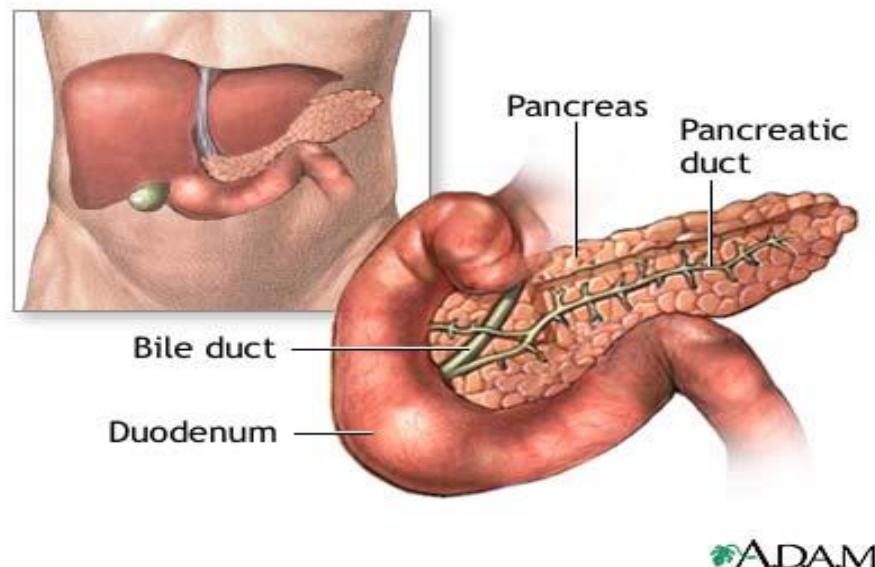

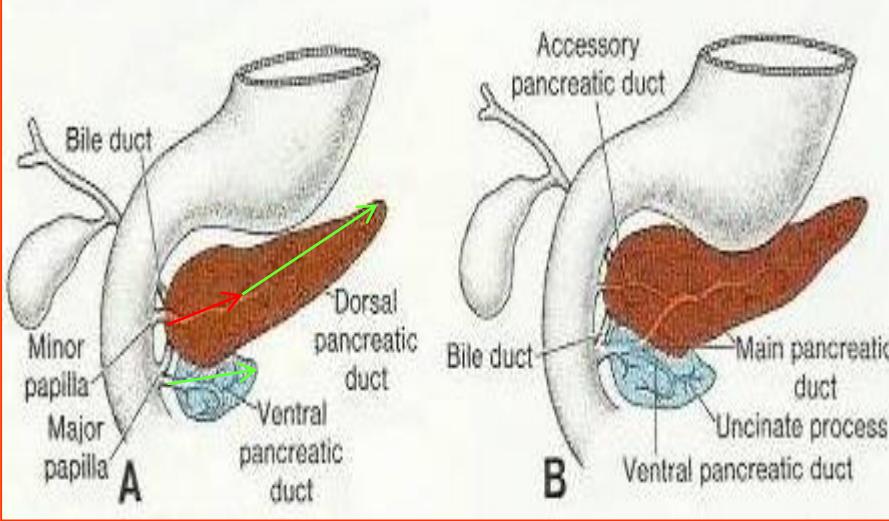

- When the **duodenum rotates to the right** and becomes C-shaped, the **ventral pancreatic bud** moves dorsally to lie **below and behind** the dorsal bud.
- Later the **2 buds fused together** and lying in the dorsal mesentery.

# DEVELOPMENT OF PANCREAS

- **The ventral bud forms :**
  - Uncinate process.
  - Inferior part of head of pancreas.
- **The dorsal pancreatic bud forms :**
  - Upper part of head.
  - Neck.
  - Body &
  - Tail of pancreas.

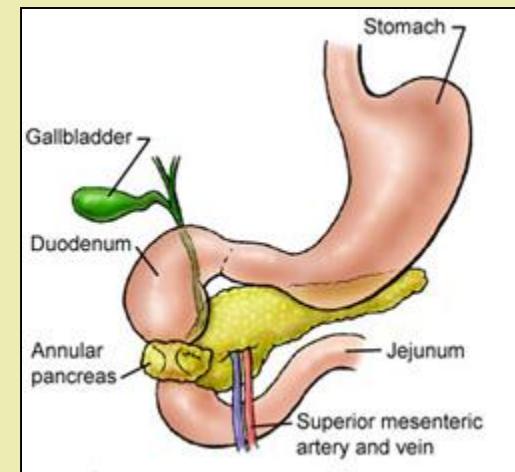

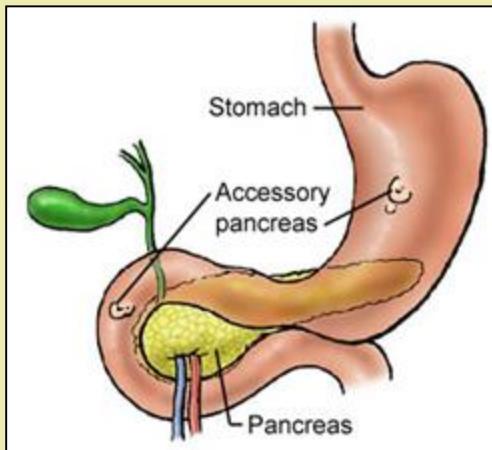

# DEVELOPMENT OF PANCREAS

- **The main pancreatic duct is formed from :**
  - The duct of the **ventral bud**.
  - The distal part of duct of **dorsal bud**.
- **The accessory pancreatic duct is derived from :**
  - Proximal part of duct of **dorsal bud**.
- **The parenchyma of pancreas** is derived from the **endoderm** of pancreatic buds.
- **Pancreatic islets** develops from parenchymatous pancreatic tissue.
- **Insuline secretion** begins at 5<sup>th</sup> month of pregnancy.

# Congenital anomalies

- **Accessory pancreatic tissue**; located in the wall of the stomach or duodenum.
- **Anular pancreas**; a thin flat band of pancreatic tissue surrounding the second part of the duodenum, causing **duodenal obstruction**.

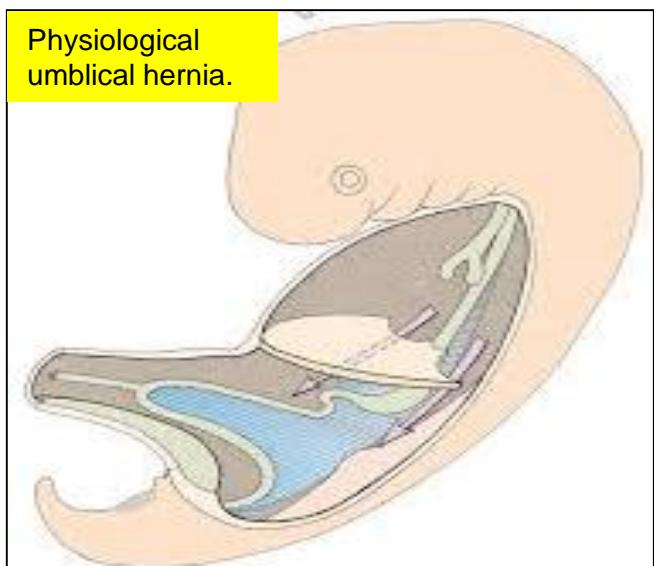

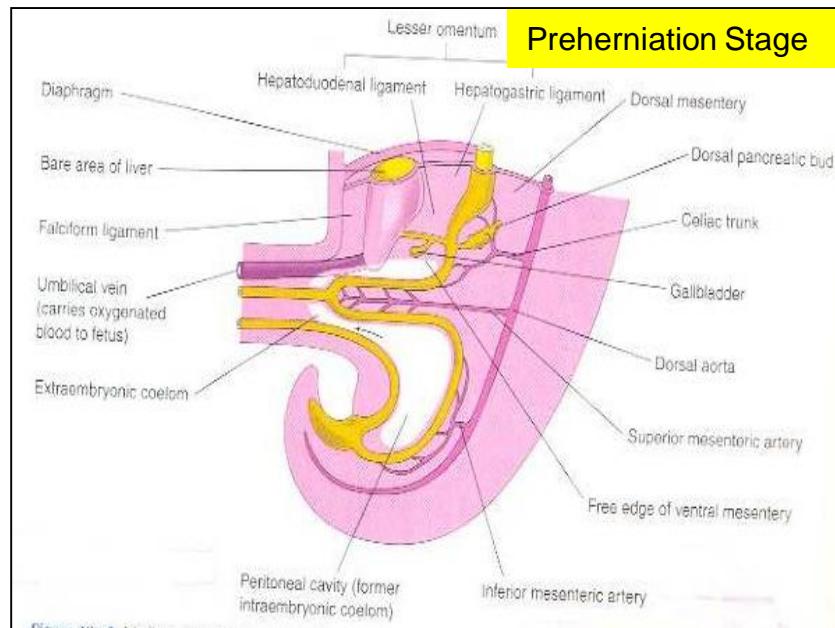

# DEVELOPMENT OF SMALL INTESTINE

- **Derivatives of cranial part of the midgut loop :**
- **Distal part of the duodenum (proximal part of duodenum is developed from caudal part of foregut)**
- Jejunum
- Upper part of the ileum.
- **Derivatives of the caudal part of midgut loop :**
- Lower portion of ileum.
- Cecum & appendix.
- Ascending colon + proximal 2/3 of transverse colon.
- **So, the small intestine is developed from :**
- **Caudal part of foregut.**
- **All midgut.**
- **Midgut is supplied by** superior mesenteric artery (artery of midgut).

# STAGES OF DEVELOPMENT OF SMALL INTESTINE

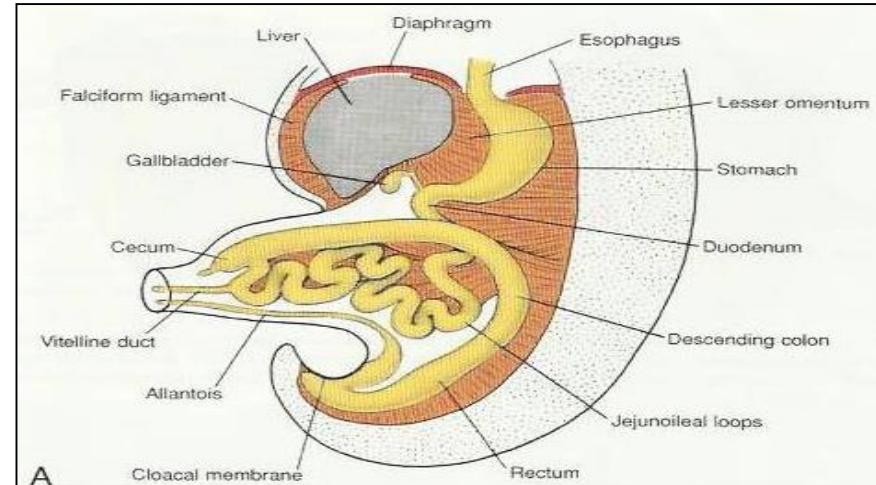

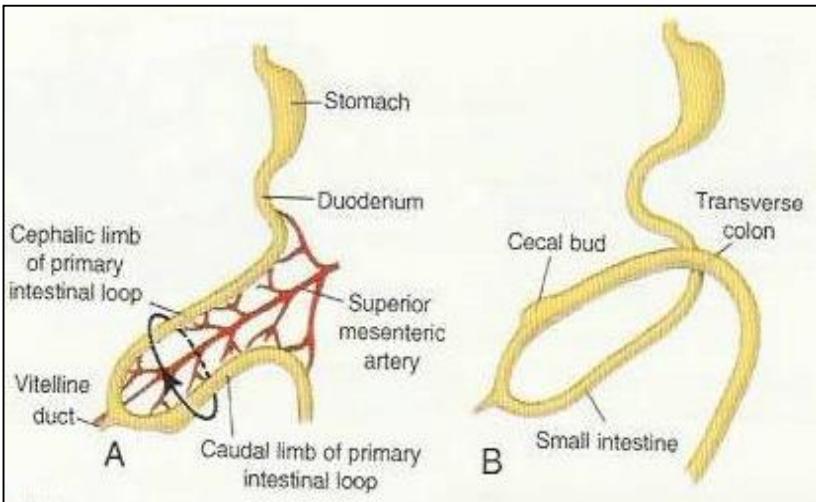

- Preherniation stage.
- Stage of physiological umbilical hernia.
- stage of rotation of midgut loop.
- Stage of reduction of umbilical hernia.
- Stage of fixation of various parts of intestine.

# Development of midgut loop

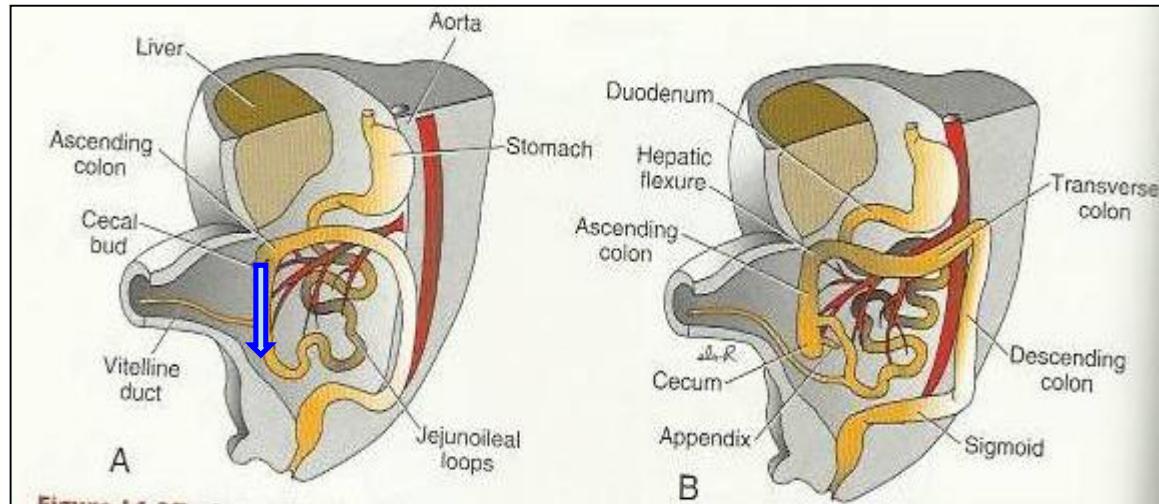

- At the beginning of 6<sup>th</sup> week, the midgut elongates to form a ventral U-shaped midgut loop.
- Midgut loop communicates with the yolk sac by vitelline duct or yolk stalk.
- As a result of rapidly growing liver, kidneys & gut, the abdominal cavity is temporarily too small to contain the developing rapidly growing intestinal loop.
- So ,Midgut loop projects into the umbilical cord ...this is called **physiological umbilical herniation (begins at 6<sup>th</sup> w.)**.

# ROTATION OF THE MIDGUT LOOP

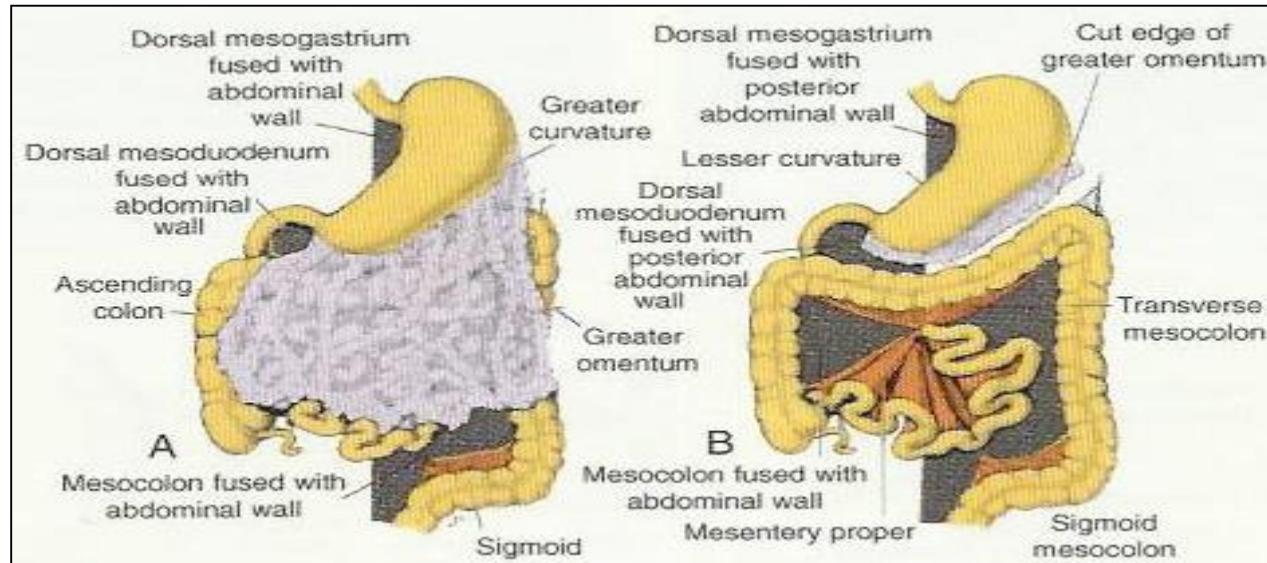

- Midgut loop has a cranial limb & a caudal limb.
- Midgut loop rotates around the axis of the superior mesenteric artery.
- Midgut loop rotates first 90 degrees to bring the cranial limb to the right and caudal limb to left during the physiological hernia.
- The cranial limb of midgut loop elongates to form the intestinal coiled loops (jejunum & ileum).
- This rotation is counterclockwise and it is completed to 270 degrees, so after reduction of physiological hernia it rotates to about 180 degrees.

# RETURN OF MIDGUT TO ABDOMEN

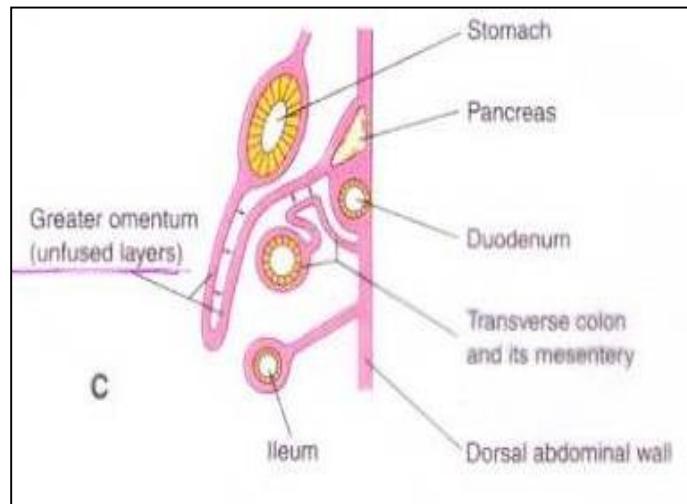

- During 10<sup>th</sup> week, the intestines return to the abdomen due to regression of liver & kidneys + expansion of abdominal cavity. It is called **reduction of physiological midgut hernia**.
- Rotation is completed and the coiled intestinal loops lie in their final position in the left side.
- The caecum at first lies below the liver, but later it **descends** to lie in the **right iliac fossa**.

# FIXATION OF VARIOUS PARTS OF INTESTINE

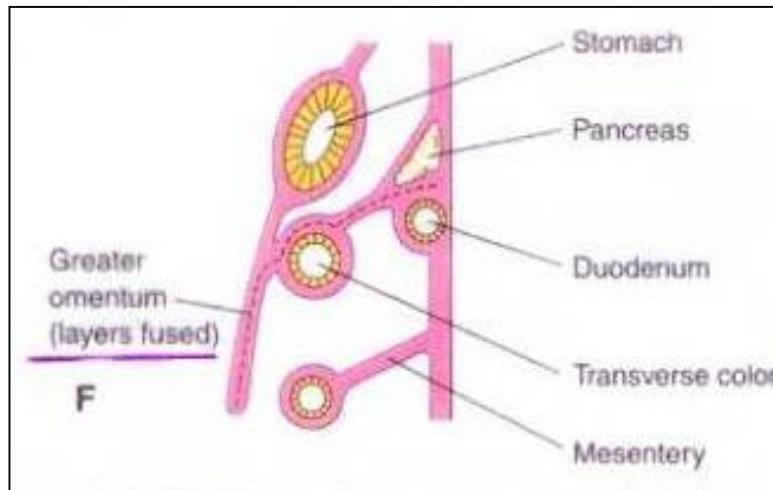

- **The mesentry of jejunileal loops** is at first continuous with that of the ascending colon.
- When the **mesentry of ascending colon fuses with the posterior abdominal wall**, **the mesentry of small intestine** becomes **fan-shaped** and acquires a new line of attachment that passes from duodenojejunal junction to the ileocecal junction.

# Fixation of various parts of intestines

Intestines prior to fixation

Intestines after fixation

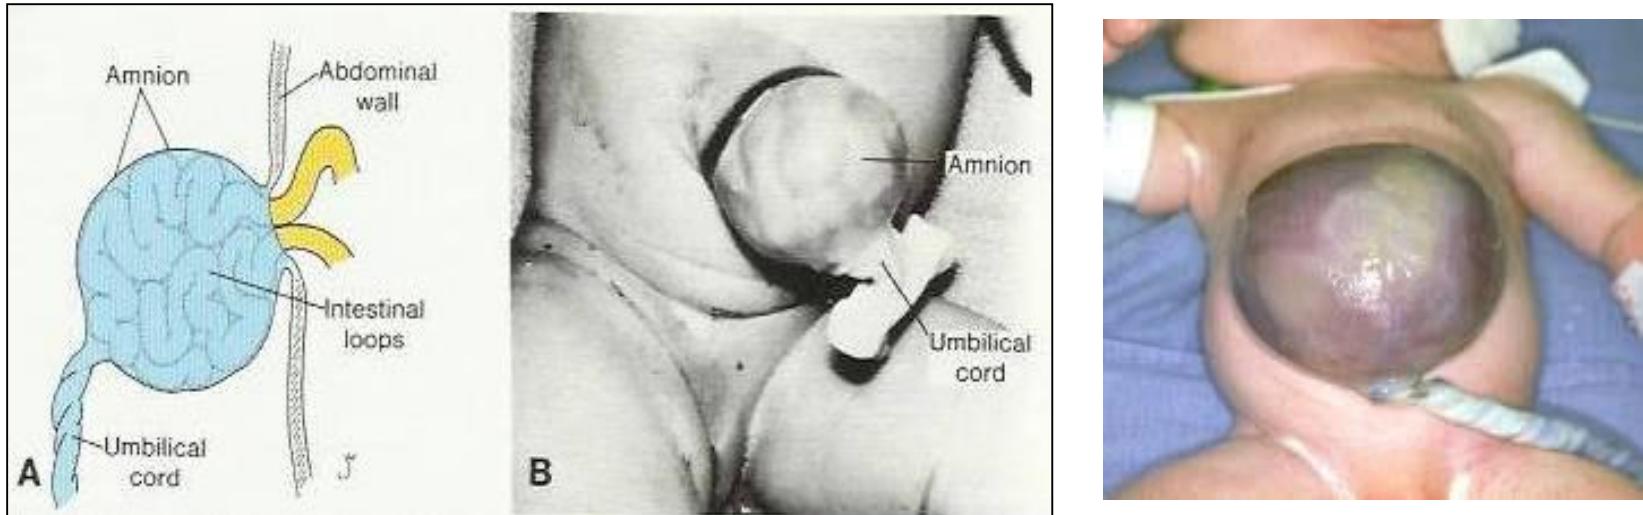

➤ The enlarged colon presses the duodenum & pancreas against the posterior abdominal wall.

**C & F**

➤ Most of duodenal mesentery is absorbed, so most of duodenum ( except for about the first 2.5 cm derived from foregut) & pancreas become retroperitoneal.

**C & F**

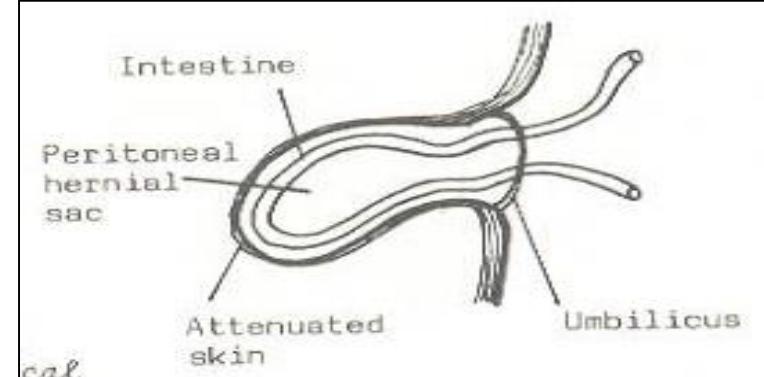

# Congenital Omphalocele

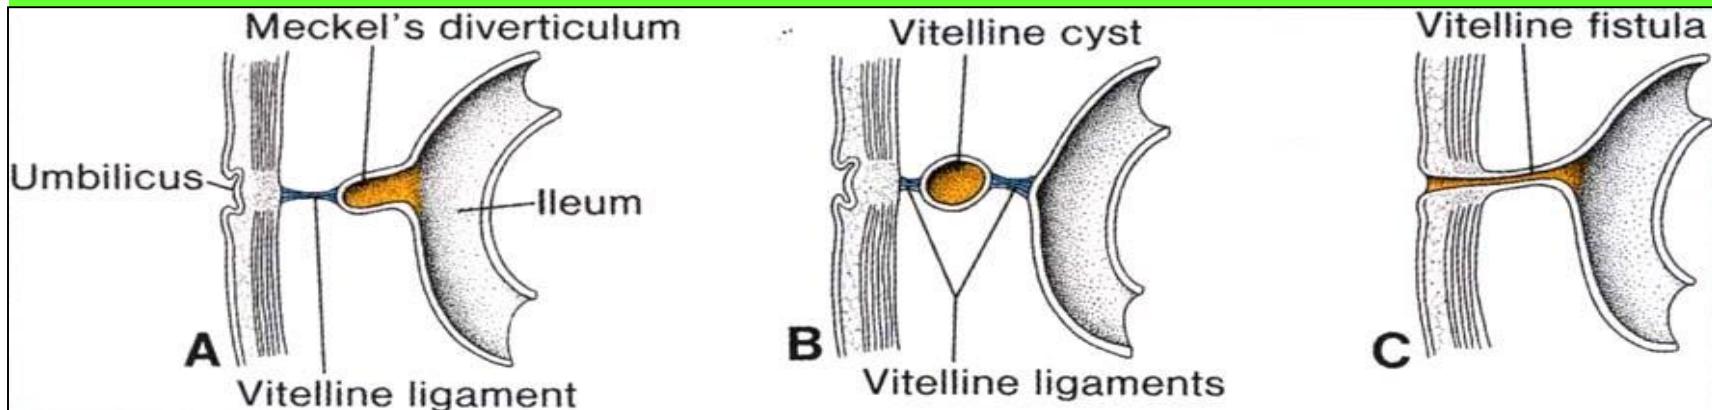

- It is a persistence of herniation of abdominal contents into proximal part of umbilical cord due to failure of reduction of physiological hernia to abdominal cavity at 10th week.
- Herniation of intestines occurs in 1 of 5000 births – herniation of liver & intestines occurs in 1 of 10,000 births.
- It is accompanied by small abdominal cavity.
- The hernial sac is covered by the epithelium of the umbilical cord/ the amnion.
- Immediate surgical repair is required.

# Congenital Umbilical Hernia

- The intestines return to abdominal cavity at 10th week, but herniated through an imperfectly closed umbilicus
- It is a common type of hernia.
- The herniated contents are usually the greater omentum & small intestine.
- The hernial sac is covered by skin & subcutaneous tissue.
- It protrudes during crying, straining or coughing and can be easily reduced through fibrous ring at umbilicus.
- Surgery is performed at age of 3-5 years.

# Ileal (Meckel's) Diverticulum

- It is one of the most common anomalies of the digestive tract, present in about 2% -4% of people, more common in males.
- **It is a small pouch from the ileum**, and may contain small patches of gastric & pancreatic tissues causing ulceration, bleeding or even perforation.
- It is the remnant of proximal part nonobliterated part of yolk stalk (or vitelline duct).
- **It arises from antimesenteric border of ileum**, 1/2 meter from ileocecal junction.
- It is sometimes becomes **inflamed** and causes symptoms that mimic appendicitis.
- It may be connected to the umbilicus by a fibrous cord, and the middle portion forms a cyst or may remain patent forming the fistula so, faecal matter is carried through the duct into umbilicus.

# **THANK YOU**

# SUMMARY

- The foregut gives rise to :
- **Duodenum** (proximal to the opening of the bile duct).
- **Pancreas.**
- **Biliary apparatus.**
- The pancreas develops from :
- Dorsal & ventral pancreatic buds that develop from the endodermal lining of the caudal part of foregut.

# SUMMARY

- The midgut gives rise to  
The small intestine :

- Duodenum (distal to bile duct).
- Jejunum & ileum.
- **physiological umbilical hernia :**

The midgut forms a U-shaped intestinal loop that herniates into the umbilical cord during 6<sup>th</sup> week.

- **Omphalocele** results from failure of return of the intestine into the abdomen.
- **Ileal diverticula** are common; however, only a few of them become inflamed and produce pain.

**1. Which part of the pancreas the ventral pancreatic bud forms ?**

- 1.Upper part of the head.
- 2.Lower part of the head.
- 3.Body.
- 4.Tail.

**2. Which artery the midgut loop rotates around its axis ?**

- a.Splenic artery.
- b.Inferior mesenteric artery.
- c.Superior mesenteric artery.
- d.Celiac trunk.

**3. The cranial limb of midgut loop gives rise :**

- a.The liver.
- b.The pancreas.
- c.The stomach.
- d.The jejunum & ilum.

**4. The umbilical hernia is:**

- a.Uncommon type.
- b.Resulting from imperfect closed umbilicus. 
- c.Covered by the epithelium of umbilical cord.
- d.Not be easily reduced at the umbilicus.

**5. The congenital omphalocele is :**

- a. A small pouch from the ileum.
- b.Covered by the epithelium of the umbilical cord. 
- c.An abdominal wall defect.
- d.Covered by skin.

**6. The Meckel's diverticulum :**

- a.Is a duodenal pouch.
- b.Arises from the mesenteric border of the ileum.
- c.Is a remnant of the proximal nonobliterated part of yolk stalk. 
- d.Is a physiological hernia of intestine.
