Alcohol and the brain

Prof. Hanan Hagar Pharmacology Unit College of Medicine KSU

Ethyl alcohol (ethanol)

Ethyl alcohol (ethanol) is the most commonly abused drug in the world.

Pharmacokinetics

- is a small <u>lipophilic</u> molecule
- readily crosses all biological membranes
- Rapidly & completely absorbed from GIT
- Has large Vd (distributed to all body tissues)
- Volume of distribution = Total body water (0.5-0.7 L/kg).
- Crosses placenta and excreted in milk

Metabolism of ethanol

Metabolism in gastric mucosa & liver.

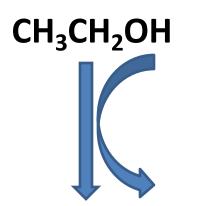

- Oxidation of ethanol to acetaldehyde via <u>alcohol dehydrogenase</u> or CYP-450 (CYP-2E1).
- Oxidation of acetaldehyde to acetate via <u>aldehyde dehydrogenase</u> which also reduces NAD+ to NADH.
- Acetate ultimately is converted to CO₂ + water.

Metabolism of ethanol

 At low ethanol conc. minor metabolism by microsomal ethanol-oxidizing system (MEOS) mainly CYP-450 (CYP2E1).

Upon continuous alcohol use, this enzyme is stimulated and contribute significantly to <u>alcohol metabolism & tolerance.</u>

Alcohol Metabolism (the major pathway) 90-98% in the liver

(Ethanol)

NAD+

Alcohol dehydrogenase , cytosolic enzyme NADH

CH₃CHO (Acetaldehyde) more toxic than alcohol

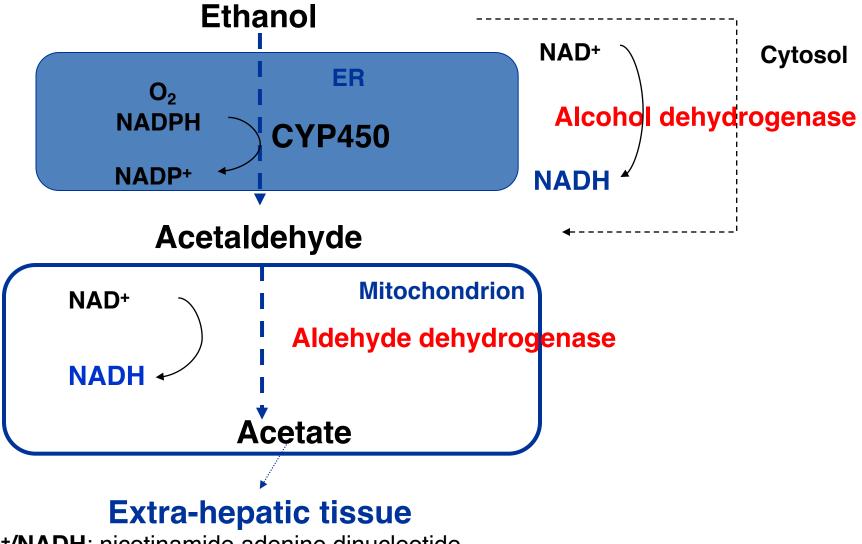

NAD+ aldehyde dehydrogenase , mitochondrial enzyme NADH

CH3COOH (Acetic acid)

Hepatic Cellular Processing of alcohol

NAD+/NADH: nicotinamide adenine dinucleotide

Metabolism of ethanol

 Acute alcohol consumption inhibits CYP450 2E1 so decrease metabolism of other drugs taken concurrently as (warfarin, phenytoin).

 Chronic alcohol consumption induces liver microsomal enzymes CYP450 2E1, which leads to significant increases in ethanol metabolism (Tolerance) & metabolism of other drugs as warfarin taken with it (Drug interactions).

Genetic variation of alcohol metabolism Aldehyde Dehydrogenase Polymorphism

- Asian populations (including Chinese, Japanese, Taiwanese, Korean) have genetic variation in aldehyde dehydrogenase resulting in a variant allele.
- The rate of metabolism of alcohol is slower than other populations.
- Can develop "Acute acetaldehyde toxicity" after alcohol intake characterized by nausea, vomiting, dizziness, vasodilatation, headache, and facial flushing and prevent them from becoming alcoholic.

Alcohol excretion

- Excreted unchanged in urine (2-8%).
- Excretion unchanged via lung (basis for breath alcohol test).
- Rate of elimination is
 - Zero-order kinetic.
 - Is not concentration-dependent.
 - i.e. rate of elimination is the same at low and high concentration.

Mechanism of action of alcohol

- It is a CNS depressants
- Acute alcohol causes:
 - Enhancement the effect of GABA (<u>inhibitory</u> <u>neurotransmitter</u>) on its GABA receptors in brain leading to CNS depression
 - Inhibition of glutamate action (<u>excitatory</u> <u>neurotransmitter</u>) on NMDA receptors leading to disruption in memory, consciousness, alertness.

Chronic alcohol leads to

up-regulation of NMDA receptors & voltage sensitive Ca channels (Ca influx to nerve cells) leading to alcohol tolerance & withdrawal symptoms (tremors, exaggerated response & seizures). Acute actions of alcohol

In mild-moderate amounts CNS depression

- relieves anxiety, euphoria (feeling of well-being).
- Nystagmus, slurred speech, impaired judgment, ataxia
- Sedation, hypnosis, loss of consciousness.

CVS depression

- Myocardial contractility depression
- Vasodilatation due to:
 - ✓ Vasomotor center depression
 - ✓ Direct smooth muscle relaxation caused by acetaldehyde

Acute actions of ethanol :

In severe amounts

- Severe CNS depression
- Respiratory depression.
- Respiratory acidosis
- Nausea, vomiting, aspiration of vomitus.
- CVS depression
- Volume depletion
- Hypotension
- Hypothermia
- Coma, death.

Chronic ethanol abuse (alcoholism) is associated with many complications

- Tolerance, dependence, addiction, behavioral changes
- Liver: hepatic cirrhosis & liver failure.
- **CVS:** hypertension, myocardial infarction
- CNS: cerebral atrophy, cerebellar degeneration, and peripheral neuropathy. <u>Wernicke encephalopathy or</u> <u>Korsakoff psychosis may occur</u>.
- **GIT system:** irritation, inflammation, bleeding, nutritional deficiencies
- Endocrine system: gynecomastia & testicular atrophy
- Hematological disorders, neoplasia.

Chronic alcohol use (Alcoholism) Liver

The most common medical complication of

alcoholism occurs with liver

- Reduction of gluconeogenesis
- Fatty liver/ alcoholic steatosis
- Hepatitis
- Hepatic cirrhosis: jaundice, ascites, bleeding, encephalopathy.
- Irreversible liver failure.

Healthy Liver

Liver in chronic alcoholics

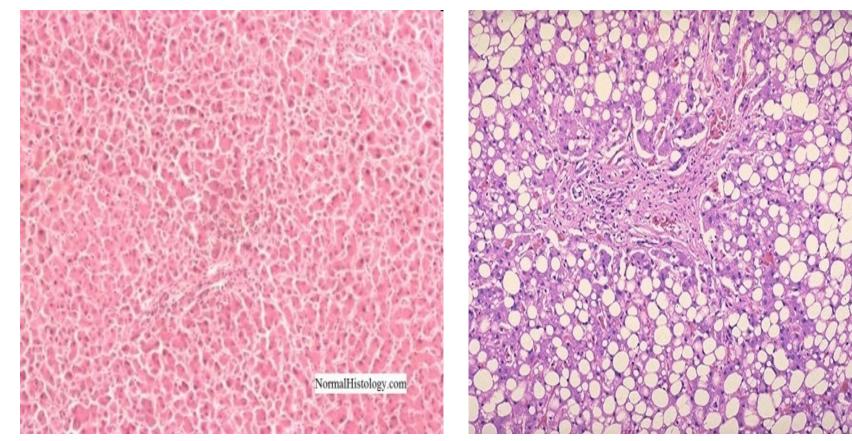

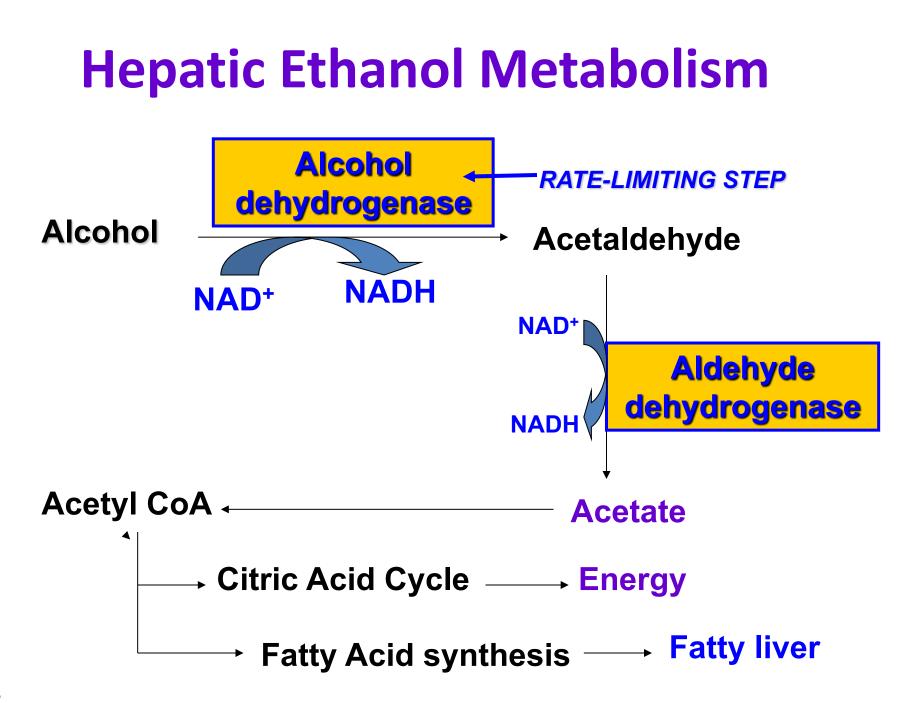

Healthy Liver vs Fatty Liver

Normal liver

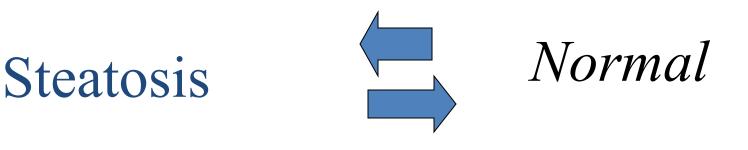

Fatty liver

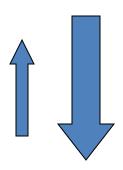

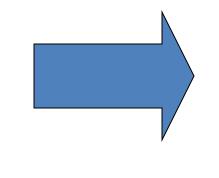

Acetaldehyde is more toxic than alcohol →causing inflammation and fat cell proliferation

Alcoholic Liver Disease

Steatohepatitis

Gastrointestinal system

- Gastritis, hemorrhagic esopahgitis, ulcer diseases, pancreatitis (due to direct toxic action on epithelium).
- Diarrhea
- Deficiency of vitamins.
- Exacerbates nutritional deficiencies
- weight loss, and malnutrition
- In heavy drinkers: increased risk of oral and esophageal cancer.

Cardiovascular System

Chronic alcohol abuse can lead to cardiomyopathy

- Cardiac hypertrophy
- Congestive heart failure.
- Arrhythmia (due to potassium and magnesium depletion)
- **Hypertension**: due to increased calcium & sympathetic activity.

Hematological complications:

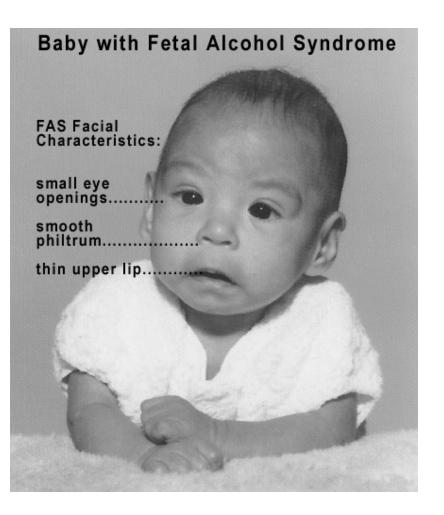

- **Iron deficiency anemia** (due to inadequate dietary intake & GIT blood loss).
- **Megaloblastic anemia**: (due to folate deficiency, malnutrition, impaired folate absorption).
- Hemolytic anemia.
- Bone marrow suppression
- **Thrombocytopenia** (suppressing platelet formation, prolong bleeding times).
- Impaired production of vitamin-K dependent clotting factors leading to prolonged prothrombin time.

Fetal Alcohol Syndrome: Irreversible

- Ethanol rapidly crosses placenta
- Pre-natal exposure to alcohol causes:
 - Intrauterine growth retardation (due to hypoxia)
- Congenital malformation (teratogenesis):
 - Microcephaly
 - Impaired facial development
 - Congenital heart defects
 - Physical and mental retardation.

Fetal Alcohol Syndrome (FAS)

The right brain is an infant's brain that had pre-natal exposure to alcohol.

Endocrine system: > Hypogonadism:

In women: ovarian dysfunction, amenorrhea, anovulation, hyperprolactinemia, infertility.

In men: gynecomastia, decreased muscle & bone mass, testicular atrophy, sexual impotence due to inhibition of luteinizing hormone (LH), decrease in testosterone, estradiol, progesterone.

Hypoglycemia & ketoacidosis due to impaired hepatic gluconeogenesis & excessive lipolytic factors, especially increased cortisol and growth hormone.

Central Nervous System

Tolerance

- Physiological and psychological dependence
- Addiction: dopamine, serotonin and opioids are involved.
- Neurologic disturbances
- Wernicke-Korsakoff syndrome

Wernicke-Korsakoff syndrome

- It is a combined manifestation of **two** disorders: **Wernicke's encephalopathy**: characterized by
- ocular disturbances unsteady gait
- changes in mental state as confusion, delirium, ataxia
 - **Korsakoff's psychosis:** impaired memory & cognitive and behavioral dysfunction.
 - Cause: thiamine (vitamin B1) deficiency due to: inadequate nutritional intake decreased uptake of thiamine from GIT decreased liver thiamine stores Treated by: thiamine + dextrose-containing IV fluids. 27

Alcoholism Tolerance

Chronic consumption of alcohol leads to tolerance That develops due to:

Metabolic tolerance (pharmacokinetic): due to induction of liver microsomal enzymes.

Functional tolerance (Pharmacodynamic): due to change in CNS sensitivity.

Alcoholism withdrawal symptoms

- Autonomic hyperactivity & craving for alcohol
- Vomiting, thirst
- Profuse sweating, severe tachycardia
- Vasodilatation, fever
- Delirium, anxiety, insomnia, agitation, tremors.
- transient visual/ auditory illusions, violent behavior, hallucinations.
- Grand mal seizures (after 7-48 hr alcohol cessation)
- Due to super-sensitivity of glutamate receptors & hypoactivity of GABA receptors are possibly involved.

Management of alcoholism withdrawal

- Substituting alcohol with a long-acting sedative/hypnotic drug then tapering the dose.
- **Benzodiazepines** as (chlordiazepoxide, diazepam) or lorazepam that is preferable (shorter duration of action).
- Efficacy: IV/ po
- Manage withdrawal symptoms & prevent irritability, insomnia, agitation & seizures.
- Dose of BDZs should be carefully adjusted to provide efficacy & avoid excessive dose that causes respiratory depression & hypotension.

Management of alcoholism withdrawal

- Fluoxetine
- Clonidine & Propranolol: inhibits the action of exaggerated sympathetic activity.
- Acamprosate: a weak NMDA receptor antagonist & GABA activator, reduce psychic craving.

To prevent alcohol relapse: Disulfiram therapy: 250 mg daily

- Disulfiram-induced symptoms that render alcoholics afraid from alcohol drinking.
- Inhibits hepatic **aldehyde dehydrogenase**, this will increase blood level of **acetaldehyde**.
- Acetaldehyde produces extreme discomfort, vomiting, diarrhea, flushing, hotness, cyanosis, tachycardia, dyspnea, palpitations & headache.

Alcohol and drug interactions

- Acute alcohol use causes inhibition of liver microsomal enzymes thus decreases metabolism of some drugs and increases their toxicities e.g. bleeding with warfarin
- Chronic alcohol use induces liver microsomal enzymes and increases metabolism of drugs such as warfarin, propranolol and etc.

 Acetaminophen + alcohol (chronic use): risk of hepatotoxicity due to increased production of free radical metabolite of acetaminophen.

- **NSAIDs + alcohol:** Increase in the risk of developing a major GIT bleeding or ulcers.
- Narcotic drugs (codeine and methadone) + alcohol: risk of respiratory and CNS depression.
- Alcohol suppresses gluconeogenesis, which may increase risk for hypoglycemia in diabetic patients.
