Treatment of Diabetes Mellitus II

Oral hypoglycemic drugs

Objectives

By the end of this lecture, students should be able to:

- 1. Classify different categories of oral hypoglycemic drugs.
- 2. Identify mechanism of action, pharmacokinetics and pharmacodynamics of each class of oral hypoglycemic drugs.
- 3. Identify the clinical uses of oral hypoglycemic drugs
- 4. Know the side effects, contraindications of each class of oral hypoglycemic drugs.

Types of diabetes mellitus

• Type I

due to autoimmune or viral diseases

• Type II

due to obesity, genetic factors

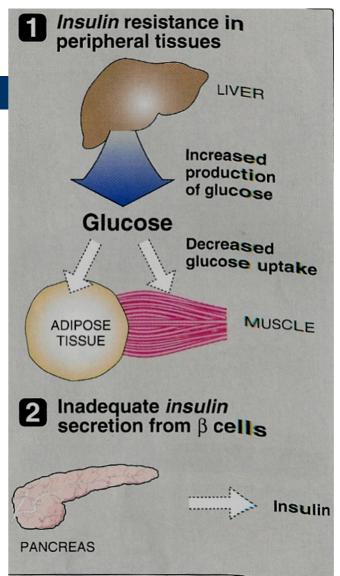

• 80-90% occurrence

• Over age 35

• **Obesity** is an important factor.

Pts with Type II diabetes have two physiological defects

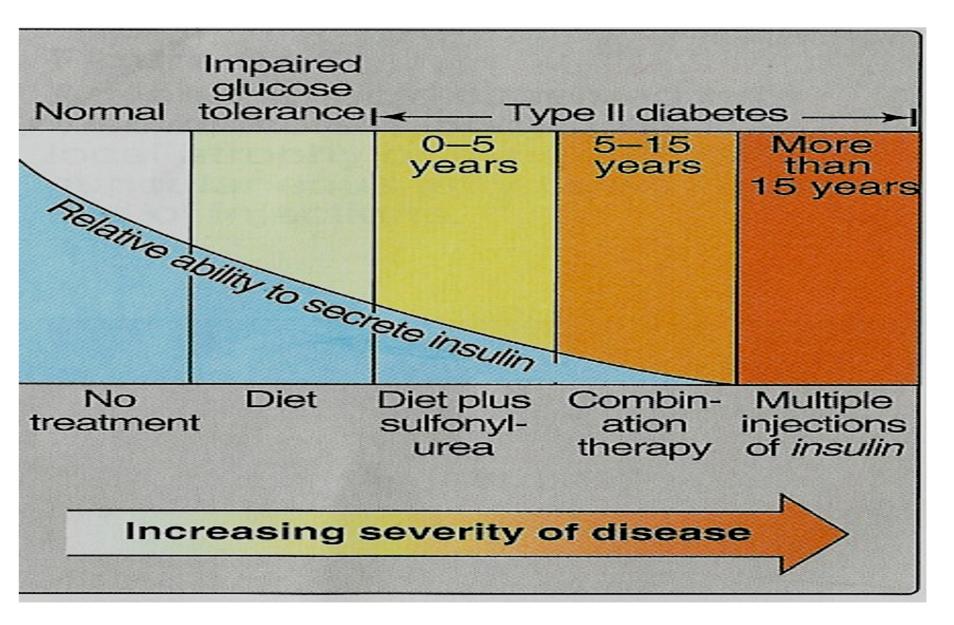

- 1. Abnormal insulin secretion
- 2. Resistance to insulin action in target tissues associated with decreased number of insulin receptors.

Treatment of Type II Diabetes (NIDDM)

- Proper dietary management.
- Caloric restriction and weight loss are important in obese diabetic patients.
- Increase physical activity.
- Antidiabetic drugs.

Types II diabetes

Antidiabetic drugs

Insulin secretagogues

- Sulfonylureas
- Meglitinides
- Incretin mimetics
- **Insulin** sensitizers
- Biguanides
- Thiazolidinediones

Note: Antidiabetic drugs = oral hypoglycemic and others

Antidiabetic drugs

Others

Agents that reduce carbohydrate absorption

Alpha glucosidase inhibitors

Agents that reduce glucose renal reabsorption

(SGLT-2, Sodium/Glucose cotransporter-2 inhibitors)

Sodium-Glucose transporter 2 (SGLT2) inhibitors

• Canagliflozin

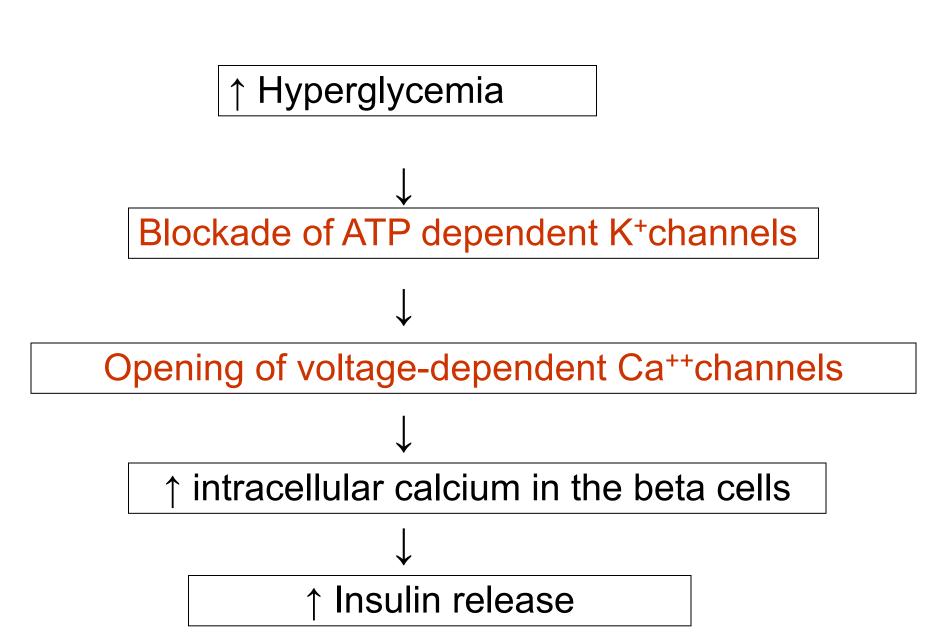

Note: Antidiabetic drugs = oral hypoglycemic and others

Insulin secretagogues

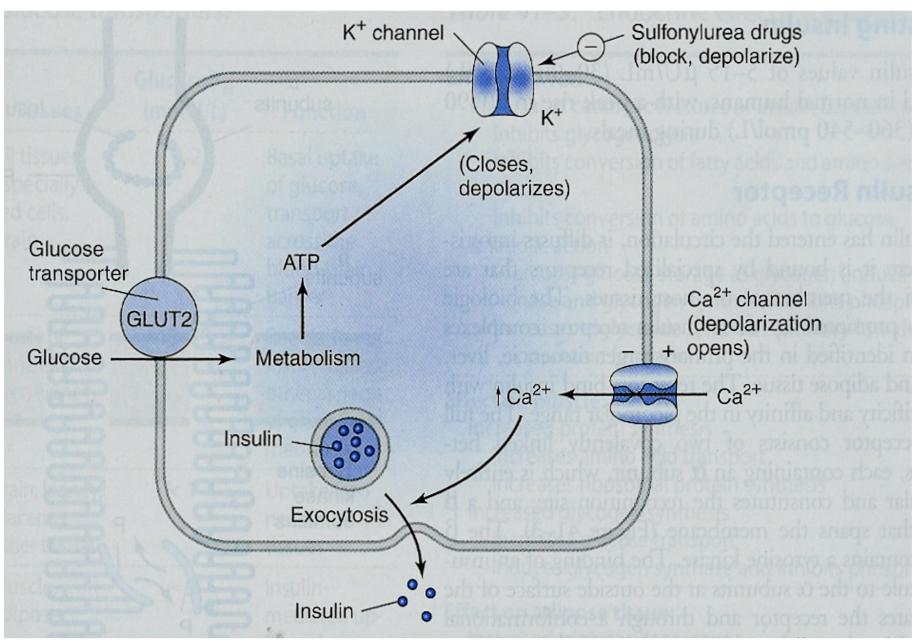

- Are drugs which increase the amount of insulin secreted by the pancreas.
- Their action depends upon functioning pancreatic β-cells
- **Include:**
- Sulfonylureas
- •Meglitinides
- Incretin mimetics

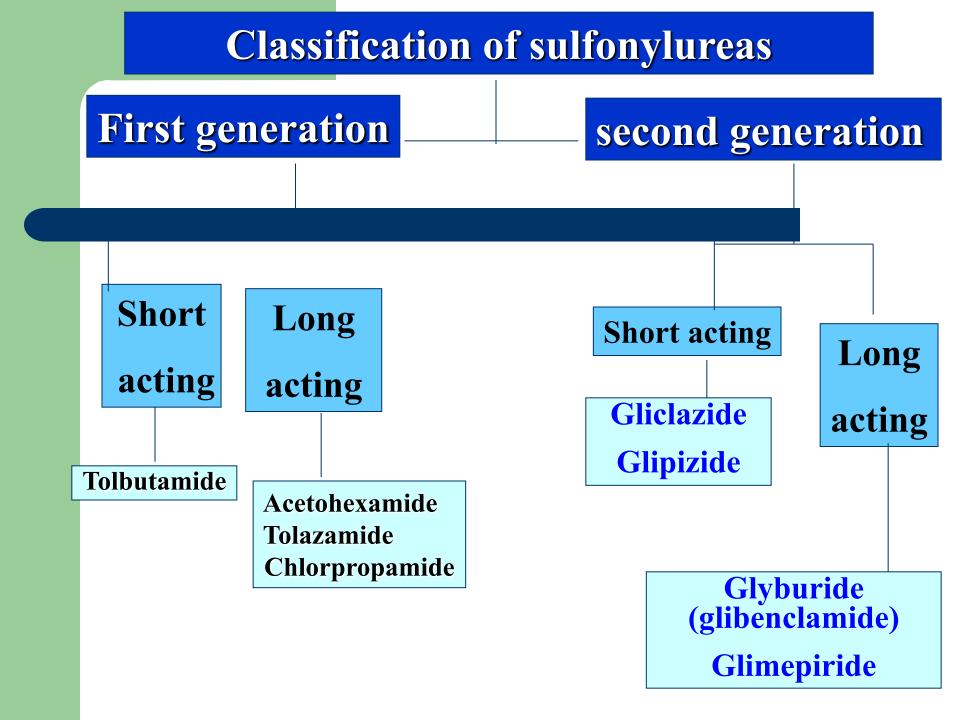

Mechanism of action of sulfonylureas:

 Stimulate insulin release from functioning B cells by <u>blocking of ATP-sensitive K channels</u> which causes depolarization and opening of voltage- dependent calcium channels, which causes an increase in intracellular calcium in the beta cells, which stimulates insulin release. Insulin secretagogues (sulfonylureas)

Mechanisms of Insulin Release

Pharmacokinetics of sulfonylureas:

- Orally, well absorbed.
- Reach peak concentration after 2-4 hr.
- All are highly bound to plasma proteins.
- Duration of action is variable.
- Metabolized in liver
- Excreted in urine (elderly and renal disease).
- Cross placenta, stimulate fetal β -cells to release insulin \rightarrow fetal hypoglycemia at birth.

Second generation sulfonylureas

Short acting: Gliclazide, Glipizide

Long acting: Glyburide, Glimepiride

- More potent than first generation
- Have longer duration of action.
- Less frequency of administration
- Have fewer adverse effects & drug interactions.

SECOND GENERATION SULPHONYLUREAS

	Glipizide	Glyburide (Glibenclamide)	Glimepiride
Absorption	Well reduced by food	Well	Well
Metabolism	Yes	Yes	Yes
Duration of action	10 – 16 hrs short	12 – 24 hrs Iong	12 – 24 hrs Iong
Doses	Divided doses 30 min before meals	Single dose	Single dose
Excretion	Urine	Urine	Urine

Uses of sulfonylureas

Treatment of Type II diabetes monotherapy or in combination with other antidiabetic drugs.

Unwanted Effects:

1. Hyperinsulinemia & Hypoglycemia:

More common in long acting sulfonylureas. particularly (glyburide, and glimepiride)
More in old age, hepatic or renal diseases.

2. Weight gain due to increase in appetite unless the diabetic diet and exercise program are followed.

Drugs

Repaglinide

Mechanism of Action:

- are rapidly acting insulin secretagogues
- Mechanism of action is identical to sulfonylureas.

Pharmacokinetics of meglitinides

- Orally, well absorbed.
- Very fast onset of action, peak 1 h.
- Short duration of action (4 h).
- Metabolized in liver and excreted in bile.
- Taken just before each meal (3 times/day) the dose should be skipped if the meal is missed.

Uses of Meglitinides

• Type II diabetes:

- monotherapy or in combination with other oral hypoglycemic drugs
- As alternative to sulfonylureas in patients allergic to sulfonylureas.

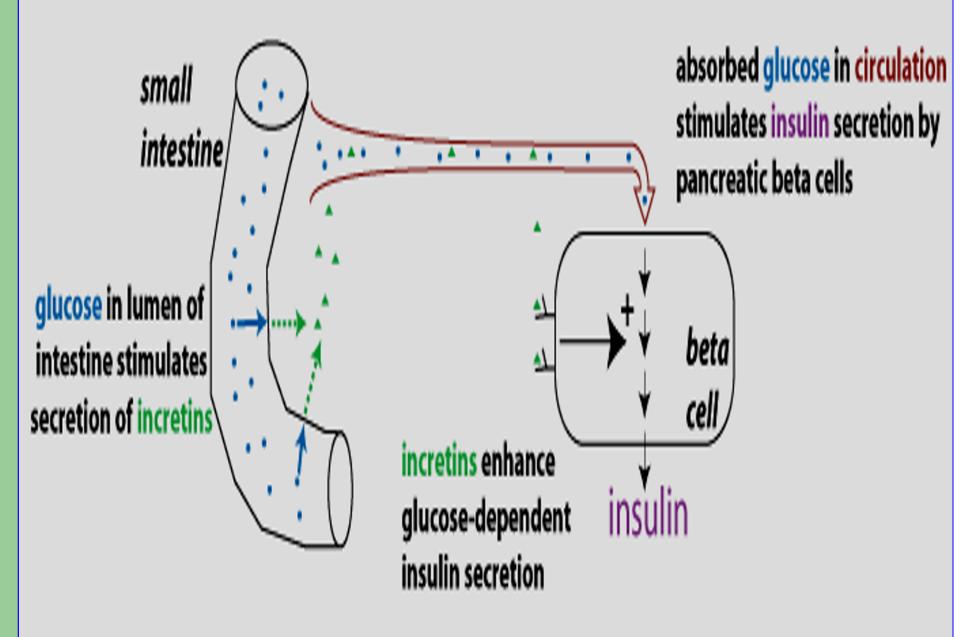

Adverse effects of Meglitinides

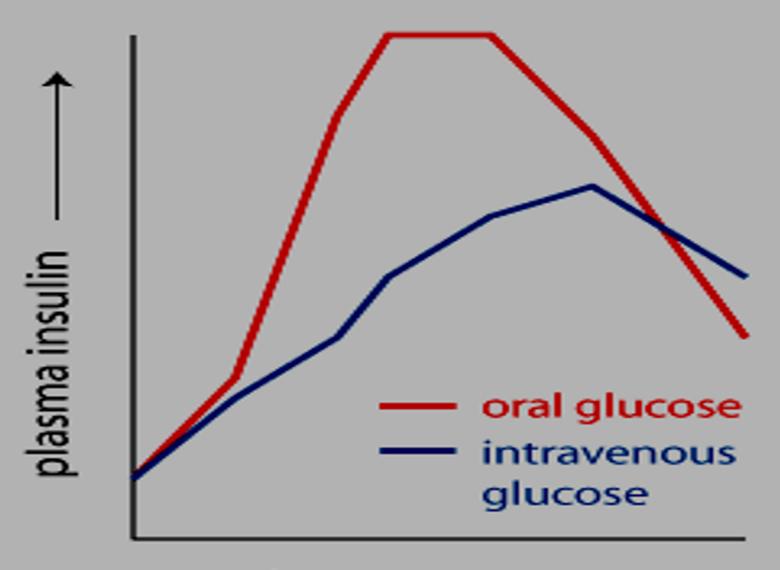

Less incidence than sulfonylureas

- Hypoglycemia.
- Weight gain.

Incretins

- Incretins are GI hormones secreted from intestine in response to food even before blood glucose level becomes elevated. They are carried through circulation to pancreatic beta cells.
- Incretins regulate blood glucose by:
 - Increasing insulin secretion
 - Decreasing glucagon secretion

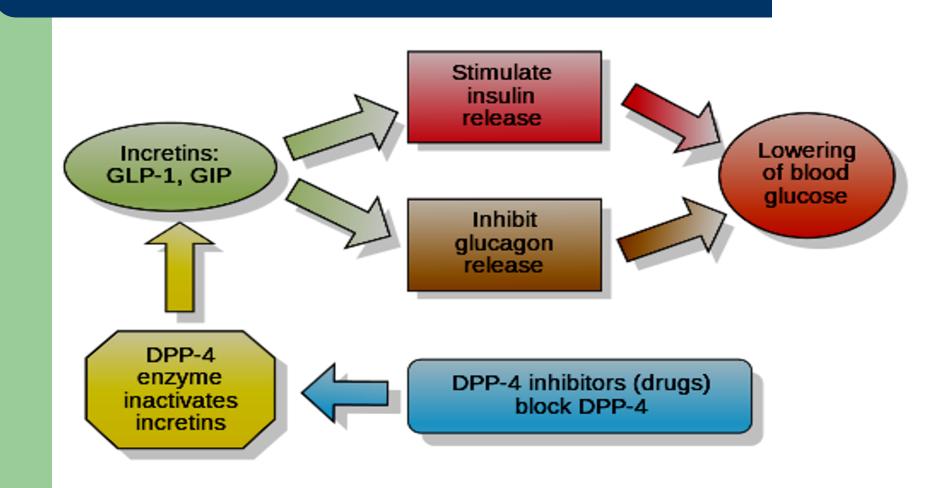

Incretins

 Incretins include: GLP-1 (Glucagon-Like Peptide-1)
 GIP (Gastric Inhibitory Peptide)
 GIP= also called glucose-dependent insulinotropic peptide

Both are inactivated by dipeptidyl peptidase-4 (DPP-4).

Mechanism of action of incretin mimetics

Incretins mimetics (Glucagon-like peptide-1 agonists) (GLP-1 agonists)

GLP-1 drugs are non-insulin treatments for people with type 2 diabetes.

Include:

- Exenatide
- Dulaglutide (Trulicity)
- Liraglutide (Victoza, Saxenda)^R,
- Semaglutide (Rybelsus®) 1st oral GLP-1 agonist

GLP-1 agonists Liraglutide (Victoza, Saxenda)^R

Mechanism of action

- Binds to GLP-1 receptors & stimulates insulin secretion from β cells.
- Inhibits alpha cells of the pancreas.
- Reduces glucagon secretion
- Decreases appetite & decreases body weight gain.

GLP-1 agonists Liraglutide (Victoza, Saxenda)^R

- Liraglutide
 - Victoza®, is the lower dose for diabetes
 Saxenda®, is the higher dose for obesity
- given s.c. once/day
- given as single- dose pre-filled disposable pens
- Used together with diet and exercise to treat type 2 diabetes and in patients who are not controlled with other oral antidiabetics.
- Not used in type I diabetes.

GLP-1 agonists Liraglutide (Victoza, Saxenda)^R

Liraglutide (saxenda) used for treatment of obesity in adults who are overweight with at least one weight-related comorbid condition (e.g. hypertension, type 2 diabetes mellitus, or dyslipidemia).

GLP-1 agonists (Incretin mimetics)

Adverse effects

- Nausea, vomiting and diarrhea (the most common)
- Hypoglycemia when combined with sulfonylureas or insulin.
- Pancreatitis (rare)

First Oral GLP-1

Semaglutide

The first oral GLP-1 used for type 2 diabetes

https://www.fda.gov/news-events/press-announcements/fda-approves-first-oral-glp-1-treatment-type-2diabetes

Dipeptidyl peptidase-4 inhibitors (DPP- 4 inhibitors) Gliptins

e.g. Sitagliptin, vildagliptin, Linagliptin

 Gliptins inhibit DPP-4 enzyme thus increase incretin hormone (GLP-1) leading to increase in insulin secretion & decrease in glucagon secretion.

Sitagliptin

- Is given orally / once daily.

Clinical uses of DPP-4 inhibitors

Type II DM as an adjunct to diet & exercise as a monotherapy or in combination with other antidiabetic drugs.

Adverse effects

- Nausea, abdominal pain, diarrhea.
- Nasopharyngitis and headache.

Insulin sensitizers

• Are drugs which increase the sensitivity of peripheral target organs to insulin.

Include

- Biguanides e.g. metformin
- Thiazolidinediones e.g. pioglitazone

e.g. Metformin

Mechanism of action of metformin

- Reduces insulin resistance.
- Increases sensitivity of liver, muscle & adipose tissues to insulin & increase peripheral glucose utilization (tissue glycolysis).
- Inhibits hepatic glucose production (gluconeogenesis).
- Impairs glucose absorption from GIT.
- Improve lipid profile \downarrow LDL, \downarrow VLDL, \uparrow HDL

Pharmacokinetics of metformin

- orally.
- NOT bound to serum protein.
- NOT metabolized.
- $t \frac{1}{2} 3$ hours.
- Excreted unchanged in urine

Uses of metformin

- In patients with type 2 diabetes who are obese because it promotes modest weight reduction (first-line therapy).
- Type II diabetes as monotherapy or in combination.

Advantages of metformin

- No risk of hypoglycemia
- No weight gain
- has prominent lipid-lowering activity
- Inexpensive

Adverse effects of metformin

- GIT disturbances:
- Metallic taste in the mouth, nausea, vomiting, diarrhea.
- Metformin should <u>be taken with meals</u> and should be <u>started at a low dose</u> to avoid intestinal side effects then increase gradually.

Adverse effects of metformin

• Lactic acidosis (very rare)

Serious lactic acid accumulation (pH around 7.2) usually occurs only in the presence of predisposing conditions

- Renal insufficiency
- Severe liver disease
- -Alcohol abuse.
- Heart failure
- Pulmonary insufficiency
- Cardiogenic or septic shock

Adverse effects of metformin

• Interference with vitamin B₁₂ absorption (long term use).

Contraindications of metformin

- Renal disease.
- Liver disease.
- Alcoholism.
- Cardiopulmonary dysfunction.
- Pregnancy.

<u>Insulin sensitizers</u> <u>Thiazolidinediones (glitazones)</u>

- Pioglitazone
- Rosiglitazone

Mechanism of action

- Activate peroxisome proliferatoractivated receptor -γ (PPAR-γ).
- Increase sensitivity of target tissues to insulin.
- Increase glucose uptake and utilization in muscle and adipose tissue.

Pharmacokinetics of glitazones

- Orally (once daily dose).
- Highly bound to plasma albumins (99%)
- Slow onset of activity
- Half life 3-4 h
- Metabolized in liver.
- Excreted in bile and urine.

Uses of glitazones

• Type II diabetes with insulin resistance.

- Used either alone or combined with sulfonylurea, biguanides or insulin.
- No risk of hypoglycemia when used alone

Adverse effects of glitazones

- Hepatotoxicity (liver function tests for 1st year of therapy).
- Fluid retention (Edema).
- Congestive heart failure
- Mild weight gain.
- Failure of estrogen-containing oral contraceptives

<u>α-Glucosidase inhibitors</u>

- Acarbose
- Miglitol

α-Glucosidase inhibitors

- Reversible inhibitors of intestinal α -glucosidases in intestinal brush border cells that are responsible for carbohydrate digestion.
- decrease carbohydrate digestion and glucose absorption in small intestine (lower postprandial glucose level).

α-Glucosidase inhibitors

Acarbose

- Given orally
- is not absorbed.
- Excreted in feces
- Taken just before meals.
- No hypoglycemia if used alone.

Uses of α-glucosidase inhibitors

- are effective alone in the earliest stages of impaired glucose tolerance
- are not recommended alone as therapy for moderate to severe hyperglycemia
- are most useful in combination with other oral hypoglycemic drugs or with insulin.

GIT side effects: Flatulence, bloating, diarrhea, abdominal pain.

Contraindications of *α***-glucosidase inhibitors**

- Irritable bowel syndrome
- Inflammatory bowel disorders
- Intestinal obstruction.

Sodium-Glucose Transporter- 2 (SGLT2) inhibitors

Drugs as

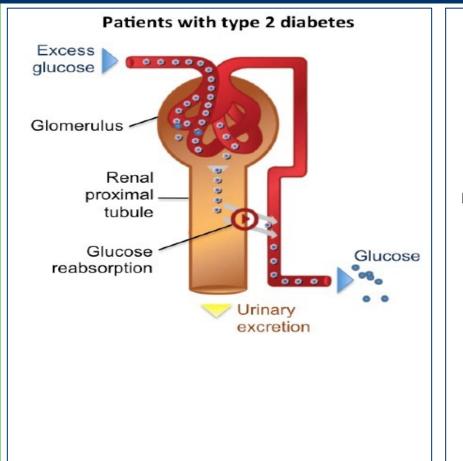

Canagliflozin, Dapagliflozin, Empagliflozin

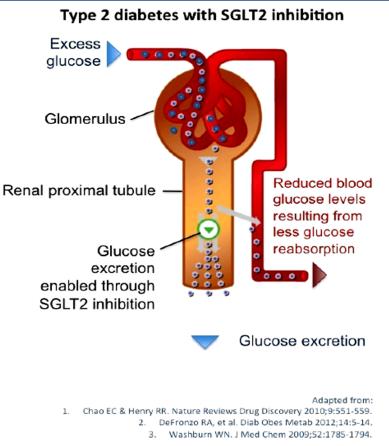

Mechanism of action:

Inhibit SGLT2 in the kidneys. This allows excess glucose to be excreted in the urine. This will reduce blood sugar levels

Mechanism of action of (SGLT2) inhibitors

Sodium-glucose transporter- 2 (SGLT2) inhibitors

USES

- Used with diet and exercise to control high blood sugar in patients with type 2 diabetes.
- To reduce risk of major adverse cardiovascular events in adults with T2DM and established cardiovascular disease.

Side effects

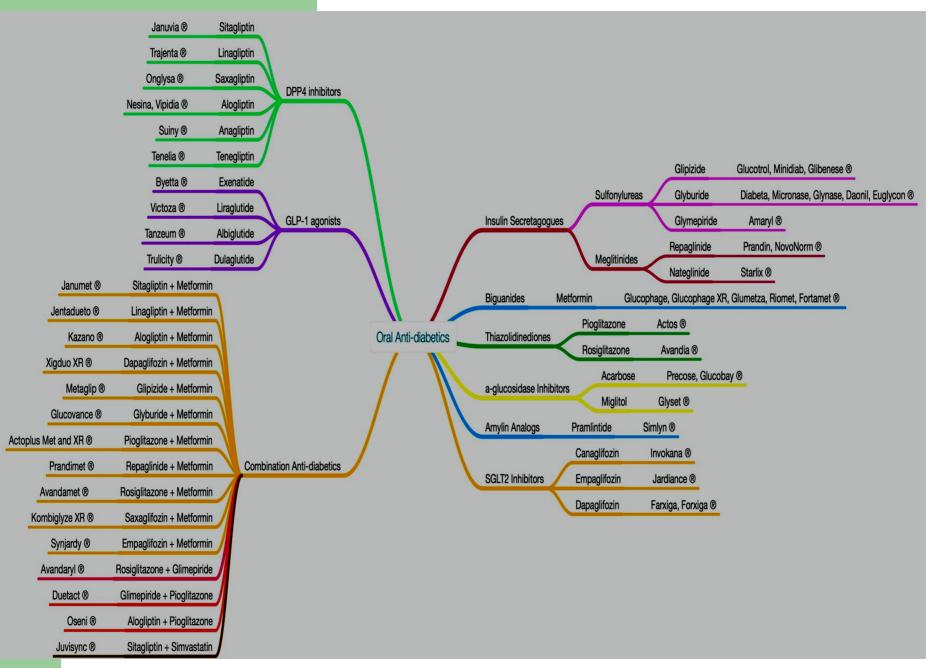

- 1) Urinary tract infections
- 2) Increased urination and dry mouth
- 3) Yeast infections (vagina or penis)
- 4) Itching (vagina or penis)
- 5) Thirst
- 6) Fatigue

SUMMARY

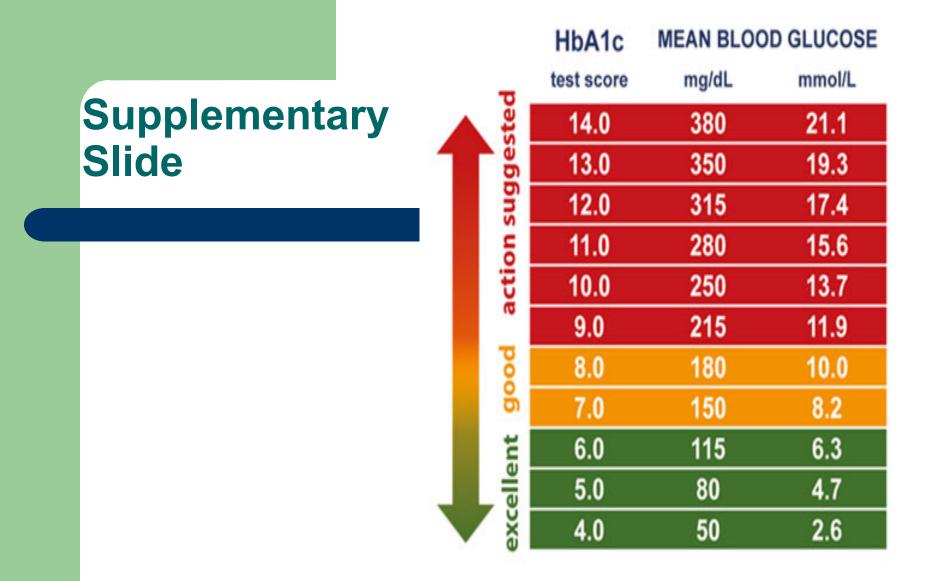

Class	Mechanism	Site of action	Main advantages	Main side effects
Sulfonylureas	Insulin Secretagougues Stimulate insulin secretion	Pancreatic beta cells	 Effective Inexpensive	 Hypoglycemia Weight gain
Meglitinides repaglinide		Pancreatic beta cells	Sulfa free	 Hypoglycemia Weight gain
Incretins mimetics Glucagon-like peptide-1 agonists (GLP-1 agonists) Dulaglutide Liraglutide Exenatide	Increase incretin thus	GI tract	Once/day, s.c.	Nausea & vomiting
DPP-4 inhibitors Sitagliptin vildagliptin	Inhibit incretin breakdown	GI tract	orally	Nausea & abdominal pain

SUMMARY

Class	Mechanism	Site of action	Main advantages	Main side effects
Biguanides <mark>Metformin</mark>	Decreases <u>insulin</u> resistance	Liver	 mild weight loss No hypoglycemia 	 GIT symptoms, Lactic acidosis Metallic taste
Thiazolidinedione s pioglitazone		Fat, muscle	No hypoglycemia	Hepatoxicity Edema, mild weight gain
α-Glucosidase inhibitors <mark>Acarbose</mark>	Decrease glucose absorption in small intestine	GI tract	Low risk	•GI symptoms, flatulence
Sodium-glucose transporter 2 (SGLT2) inhibitors Canagliflozin	Increase renal glucose excretion	Kidney	Orally Reduced Na (CV benefits)	 UTI Increased urination and dry mouth Yeast infection Itching (vagina or penis)
