Informatics Team_{Notes}

The following slides are the original lectures. Only notes were added and they're mostly additional information. 431 team notes are in purple color and this year's notes are in green color.

For any mistakes contact informatics team leader Dana Aldubaib dsd.993@gmail.com

Notes provided by: Dana Aldubaib

Clinical Data

Amr Jamal, MD, SBFM, ABFM, MRCGP, GCMI, MBI Assistant Professor and Consultant Family Physician and Clinical Informatician Head of Medical Informatics & e-Learning Unit (MIELU) King Saud University, College of Medicine September 2014

What are clinical data? [1]

- A datum is a single observation of a patient
- Clinical data are a collection of observations about a patient
- Each datum has four elements: important
 - the patient (Amr Jamal)
 - the attribute (heart rate)
 - the value of the attribute (52 beats per minute)
 - the time of the observation (1:00 pm on 1/1/2011) or should that be 1/1/2011?

what's the important thing in the value of the attribute? the unit.

Types of clinical data [1]

- Narrative: recording by clinician- maternity history
- Numerical measurements: blood pressure, temperature
- Coded data:selection from a controlled terminology system
- Textual data: other results reported as text
- Recorded signals: EKG, EEG
- Pictures: radiographs, photographs, and other images

narrative: is another way of saying the history and examination findings coded data: the data is represented by a corresponding code.

Use of clinical data [1]

Form basis of historical record

- Support communication among providers → between cardio and radiology doctors
- Anticipate future health problems
- Record standard preventive measures
- ♦ Coding and billing → to not cheat patients and get more money out of them
- Provide a legal record
- Support clinical research → as in pandemic studies and checking trends

Types of clinical data documents [1]

History and physical examination:

by a clinician

Progress notes

update of progress by primary, consulting, and ancillary providers

Reports (pre-op, death reports, get info from past history physical)
 by specialists, ancillary providers

Typical paper chart maintains all patient notes in chronological order, sometimes separated into different components

Assessment of a stable patient [1]

Chief complaint History of the present illness Past medical history Social history Family history Review of systems Physical examination Investigations – lab, x-ray, other Assessment plan

Some complications of data [1]

Circumstances of observation

 e.g., how was heart rate taken? pulse? EKG?
 Uncertainty
 how accurate is patient reporting, measurement,
 device?

 Time

what level of specificity do we need?

Some complications of data[2]

Duplication

e.g., multiple records in different departments

Outdated

e.g. missing values

Incorrectly formatted

does not follow standards

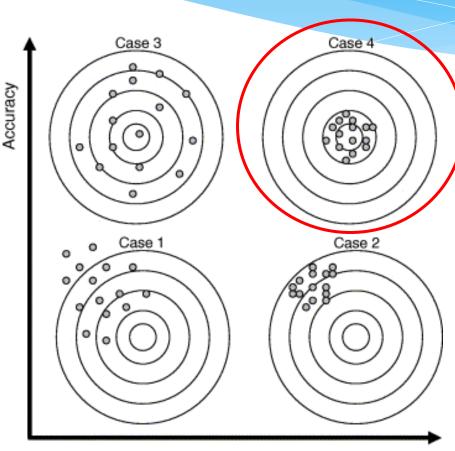

Imprecision vs. Inaccuracy

Case 1: imprecise and inaccurate

Case 2: precise and inaccurate

Case 3: imprecise and accurate

Case 4: precise and accurate

Precision

precise: results are reprod ucible (gives you same reading every time you try it)

accurate: how near is it to the truth. how accurate or true are the results.

- the center is: the truth
- the closeness or the d ot is the precision or acuity
- the dots are:
- 1. accurate: going to the middle
- 2. precise: coming near each other

Structure of clinical data [1]

- Medicine lacks uniform structured vocabulary and nomenclature
- Standardization and computerization of data is benefited by standard representations (Cimino, 2007)
- Counter-arguments are "freedom of expression" and "art of medicine" how people defend their ability to vote by not making it a standard
- Narrative information can be expressed in many ways, can be ambiguous

The Complaint:

laint(s)	1.	2.	3.
ion			

History of Presenting Illness:

We need better access to clinical data [1]

- Missing clinical information during primary care visits (Smith, 2005)
 - Information reported missing in 13.6% of clinical visits
 - Available but outside system in 52% of instances
 - Estimated to adversely effect patients 44% of time
 - Unsuccessful searching for it took >5 minutes 35% of time
- Physicians have two unmet information needs for every three patients (Gorman, 1995; Ely, 1999)
- Secondary use of clinical data (Safran, 2007)

Data entry [1]

- General categories of data entry:
 - Free-form entry by historical methods:
 - Writing using stylus
 - dictation
 - Typing
 - Structured (menu-driven) data entry by mouse or pen
 - Speech recognition for either of above

Structured or menu-driven data entry

- Many attempts from old (Greenes, 1970; Cimino, 1987; Bell, 1994) to new (Oceania; OpenSDE – Los, 2005)
- Can be done via mouse or pen, with typing
- Benefits
 - Data codified for easier retrieval and analysis
 - Reduces ambiguity if language used consistently
- Drawbacks
 - In general, more time-consuming
 - Requires exhaustive vocabulary
 - Requires dedication to use by clinicians
- Alternative: Processing free text with natural language processing and tagging text (in XML) (Johnson, 2008)

Speech recognition for data entry [1]

- Most common use is for narration
 e.g., computer dictation of clinical notes
- An advantage is instant availability of dictated c ontent
- Continuous speech recognition now is commercial reality
 - Speaker-dependent systems require user training (System only recognize voices that it's been trained for)
 - speaker-independent are systems less accurate (Cheaper, no training)
- Many established systems on the market that operate on:
 - front-end (used by clinician) or (direct by dr and transfer spoken to written, short time)
 - back-end (process dictations) (Brown, 2008) (need translation team, longer time for report)

Front end

Coded vs. free-text data [1]

Coded data:

- Documentation of discrete data from controlled vocabulary
- **Free text:**
 - Alphanumeric data that are unstructured, typically in narrative form

coded date means everyone around the world will represent the same code for the same disease

Narratives tell a story.

A narrative tells a story

See the patient through a description

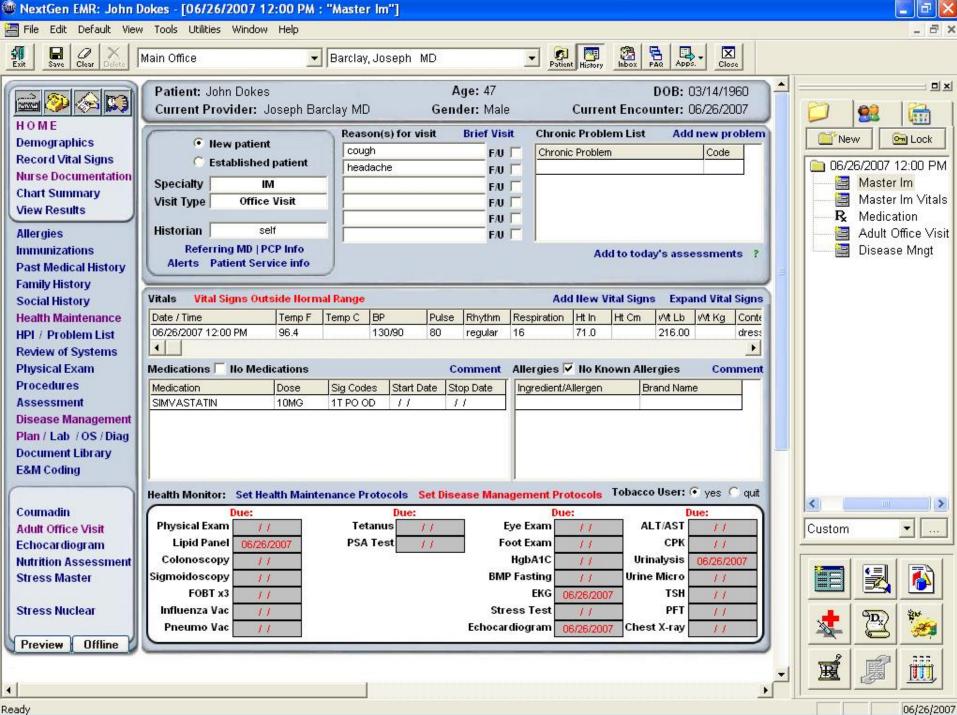

Complicated events are easier to describe in text

Undifferentiated problems

Interpretation.

"only a human can prioritize and determine what the chief complaint really is"

Issues with coded data

"pick from a list" allows wrong selection

- Compliance concerns
- Over documentation for care
- Cloning cloning:
- clinician may blindly repeat his usual selections for all of the patients

Coded clinical data enables EHR advanced functionality

- Alerts (error Alerts: to identify drug-drug interaction)
- Clinical Decision Support
- Best documentation practices
- Multi-media reporting
- Multiple output formats
- Data mining (process to explore relationships.)

Note : Much of the real and perceived b enefits of the EHR are enabled by code d clinical data. Real time alerts are signi ficant method to improve patient care a nd reduce the likelihood of errors in me dication administration and other interv entions. Clinical decision support tools are difficult to implement without struc tured data. Best documentation practic es require searchable terms and compo nents. The ability to do multi-media re porting including images and files other than text is enhanced with structured d ata. Multiple output formats such as di ffering reports for providers, patients a nd payers cannot easily be done with pr imarily text containing substrates.

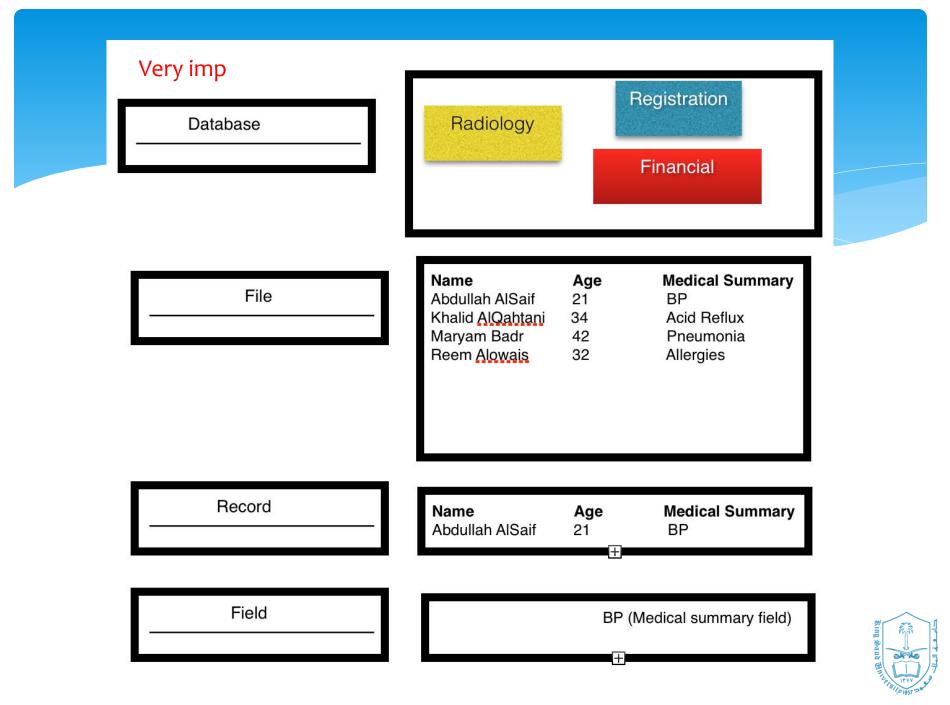

Data Management [2]

File Organization concepts

- Database: A set of related files
- File: Collection of records of same type
- Record: A set of related field
- Field: Words and numbers

Relational DBMS [1]

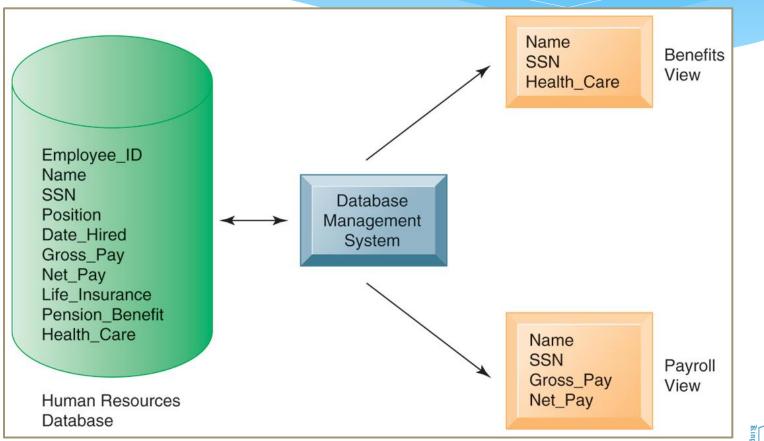

Relational model links records to tables

- Allows efficiencies
- One-time information (e.g., demographics) stored only once
- Complex queries easier to construct and carry out

Most query capabilities are based on Structured Query Language (SQL)- special language in relational database

Relational DBMS [2]

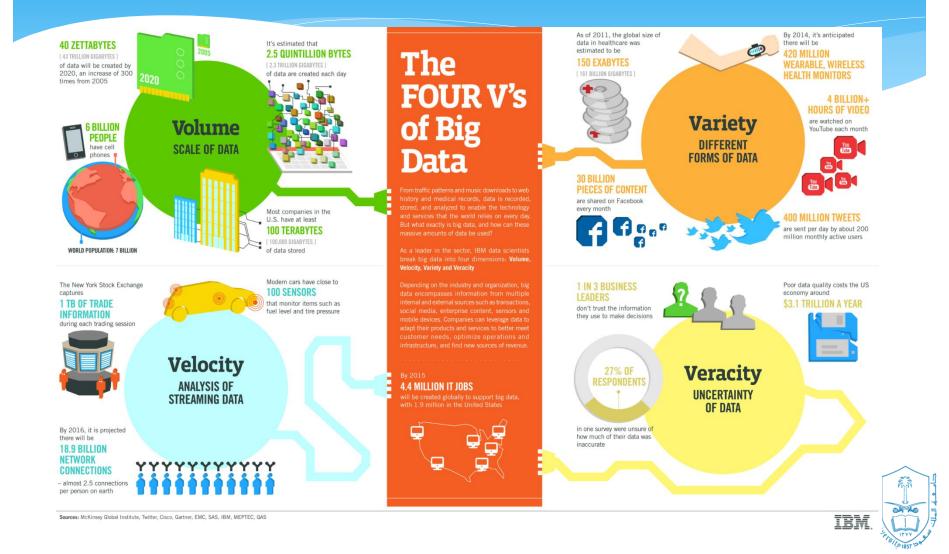

Big Data [3]

- Science of Data Management & analysis
- * "to convert Vast information and knowledge in organisation to achieve their objectives" (Murdoch et al, 2013*)
- What is BIG/VAST ? Zettabytes (10^21 gigabytes) to Yottabytes (10^24 gigabytes)
- Used in Astronomy, Search Engines, Financial, Politics and now in Biomedicine
- Example of Big Data is Bioinformatics (genome, proteomic)

The FOUR V's of Big Data [3]

Big Data in healthcare [3]

* "80% of medical data is unstructured and is clinically relevant.

The data reside in multiple places like individual EMRs, lab and imaging systems, physician notes, medical correspondence, claims, customer relations management systems and finance."

Sources of BIG DATA [4]

- Clinical Data from CPOE
- Clinical decision support systems (Written notes & prescriptions)
- Imaging systems: PACS, Radiology Information systems
- Sensor data (monitoring vital signs)
- Social media data- Tweets from Twitter, wall and status updates on Facebook
- Emergency care data
- Literature from medical journal

Healthcare BIG data problems to be solved [4]

- * Patient profiles and the health outcomes- identify the effective treatments
- * For public health- identify individuals who would get preventive care or lifestyle changes
- * Analysing literature on medical procedure to determining which care protocols work best
- * Creating mobile apps to manage diabetes. Via Data analytics, we are able to monitor the healthcare outcomes improvements
- * Analysing social network communication among support group members- to understand how non-profit organization can interact and provide help

In summary,

Types of clinical data Types of clinical data documents Use of clinical data Access to clinical data Data entry Coded vs. free-form data Speech recognition Big Data Database Management
