Statistical tests to observe the statistical significance of qualitative variables (Z-test, Chi-square, Fisher's exact & Mac Nemar's chi-square tests)

Dr.Shaikh Shaffi Ahamed Ph.D., Professor

Dept. of Family & Community Medicine

- (1) Able to understand the factors to apply for the choice of statistical tests in analyzing the data.
- (2) Able to apply appropriately Z-test, Chi-square test, Fisher's exact test & Macnemar's Chi-square test.
- (3) Able to interpret the findings of the analysis using these four tests.

Types of Categorical Data

Qualitative/Categorical Data

Nominal Categories

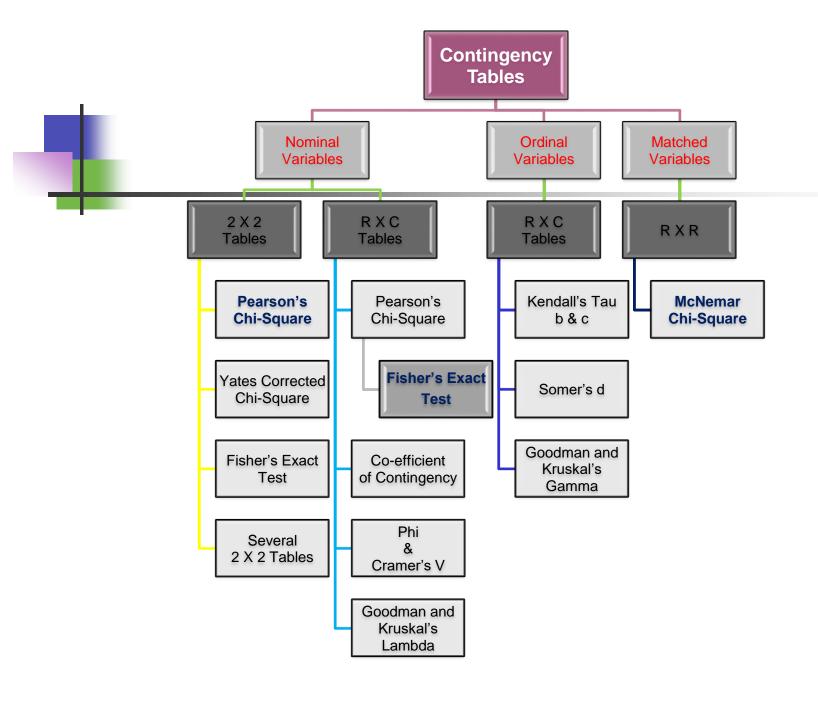

Ordinal Categories

Types of Analysis for Categorical Data

Type of Analysis

Descriptive (frequencies, percentages, rates & ratios)

Analytical
Test of Significance(p-value)
& Cl's

Choosing the appropriate Statistical test

- Based on the three aspects of the data
 - Types of variables
 - Number of groups being compared &
 - Sample size

Statistical Tests

Z-test:

Study variable: Qualitative (Categorical)

Outcome variable: Qualitative(Categorical)

Comparison:

(i)sample proportion with population proportion;

(ii)two sample proportions

Sample size: larger in each group(>30)

Test for sample proportion with population proportion **Problem**

In an Otological examination of school children, out of 146 children examined 21 were found to have some type of Otological abnormalities. Does it confirm with the statement that 20% of the school children have otological abnormalities?

a. Question to be answered:

Is the sample taken from a population of children with 20% Otological abnormality

b. Null hypothesis: The sample has come from a population with 20% Otological abnormal children

Test for sample prop. with population prop.

c. Test statistics

$$z = \frac{|p - P|}{\sqrt{\frac{pq}{n}}} = \frac{|144 - 20|}{\sqrt{\frac{144 * 856}{146}}} = 1.69$$

P – Population. Prop.

p- sample prop.

n- number of samples

d.Comparison with theoritical value

$$Z \sim N(0,1); Z_{0.05} = 1.96$$

The prob. of observing a value equal to or greater than 1.69 by chance is more than 5%. We therefore do not reject the Null Hypothesis

e. Inference

There is a evidence to show that the sample is taken from a population of children with 20% abnormalities

Problem

In a community survey, among 246 town school children, 36 were found with conductive hearing loss and among 349 village school children 61 were found with conductive hearing loss. Does this data, present any evidence that conductive hearing loss is as common among town children as among village children?

a. Question to be answered:

Is there any difference in the proportion of hearing loss between children living in town and village?

Given data	sample 1	sample 2
size	246	342
hearing loss	36	61
% hearing loss	14.6 %	17.5%

b. Null Hypothesis

There is no difference between the proportions of conductive hearing loss cases among the town children and among the village children

C. Test statistics

$$z = \frac{|p1-p2|}{\sqrt{\frac{p1q1}{n1} + \frac{p2q2}{n2}}} \qquad \mathbf{q} = \mathbf{1} - \mathbf{p}$$

p1, p2 are sample proportions, n1,n2 are subjects in sample 1 & 2

$$= \frac{|146-17.5|}{\sqrt{\frac{144*856}{246} + \frac{17.5*825}{342}}} = 1.81$$

Comparison with theoretical value

$$Z \sim N(0,1); Z_{0.05} = 1.96$$

The prob. of observing a value equal to or greater than 1.81 by chance is more than 5%. We therefore do not reject the Null Hypothesis

e. Inference

There is no evidence to show that the two sample proportions are statistically significantly different. That is, there is no statistically significant difference in the proportion of hearing loss between village and town, school children.

Statistical test (cont.)

Chi-square test:

Study variable: Qualitative(Categorical)

Outcome variable: Qualitative(Categorical)

Comparison: two or more proportions

Sample size: >30

Expected frequency: > 5

Chi-square test Purpose

To find out whether the association between two categorical variables are statistically significant

Null Hypothesis

There is no association between two variables

$$X^2 = \frac{\left(o - e\right)^2}{e}$$

Figure for Each Cell

The summation is over all cells of the contingency table consisting of r rows and c columns

- 2. O is the observed frequency
- 3. È is the expected frequency

$$\hat{E} = \frac{\text{total of row in which the cell lies} \cdot \text{(total of all cells)}}{\text{(total of all cells)}}$$

reject
$$H_0$$
 if $\chi^2 > \chi^2_{.\alpha,df}$
where df = $(r-1)(c-1)$

$$\chi^2 = \sum \frac{(O-E)^2}{E}$$

4. The degrees of freedom are df = (r-1)(c-1)

- Prior to using the chi square test, there are certain requirements that must be met.
 - The data must be in the form of frequencies counted in each of a set of categories. Percentages cannot be used.
 - The total number observed must be exceed 20.

- The expected frequency under the H₀ hypothesis in any one fraction must not normally be less than 5.
- All the observations must be independent of each other. In other words, one observation must not have an influence upon another observation.

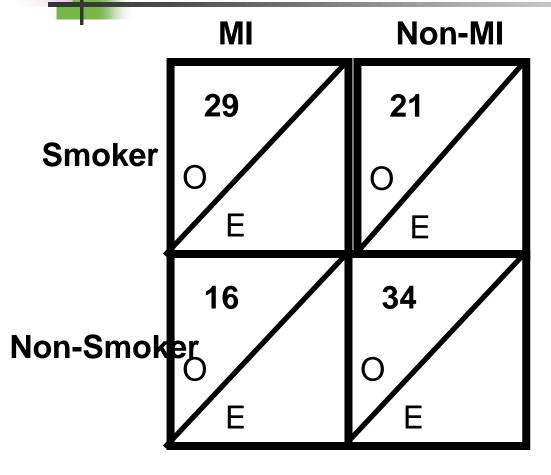

APPLICATION OF CHI-SQUARE TEST

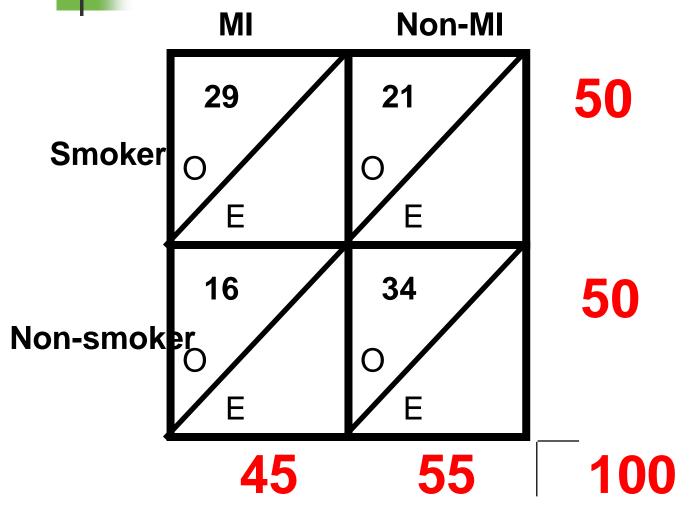

- TESTING INDEPENDENT (or ASSOCATION)
- TESTING FOR HOMOGENEITY
- TESTING OF GOODNESS-OF-FIT

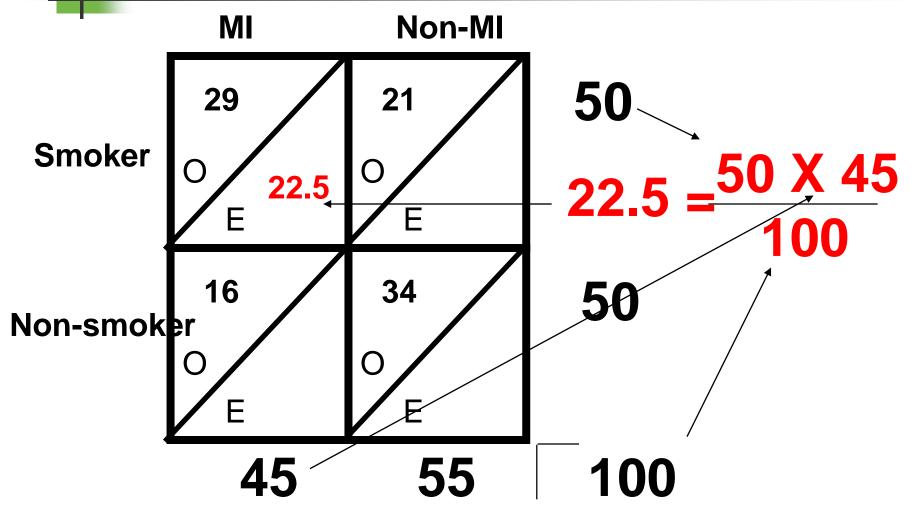

- Objective : Smoking is a risk factor for MI
- Null Hypothesis: Smoking does not cause MI

	D (MI)	No D(No MI)	Total
Smokers	29	21	50
Non-smokers	16	34	50
Total	45	55	100

Chi-Square

Degrees of Freedom df = (r-1) (c-1)= (2-1) (2-1) =1

Critical Value (Table A.6) = 3.84

$$X^2 = 6.84$$

Calculated value(6.84) is greater than critical (table) value (3.84) at 0.05 level with 1 d.f.f

Hence we reject our Ho and conclude that there is highly statistically significant association between smoking and MI.

Background:

Contradictory opinions:

 1. A diabetic's risk of dying after a first heart attack is the same as that of someone without diabetes. There is no association between diabetes and heart disease.

VS.

- 2. Diabetes takes a heavy toll on the body and diabetes patients often suffer heart attacks and strokes or die from cardiovascular complications at a much younger age.
- So we use hypothesis test based on the latest data to see what's the right conclusion.
- There are a total of 5167 patients, among which 1131 patients are non-diabetics and 4036 are diabetics. Among the non-diabetic patients, 42% of them had their blood pressure properly controlled (therefore it's 475 of 1131). While among the diabetic patients only 20% of them had the blood pressure controlled (therefore it's 807 of 4036).

Data

	Controlled	Uncontrolled	Total
Non-diabetes	475	656	1131
Diabetes	807	3229	4036
Total	1282	3885	5167

Data:

Diabetes: 1=Not have diabetes, 2=Have Diabetes

Control: 1=Controlled, 2=Uncontrolled

DIABETES * CONTROL Crosstabulation

Count

	CONTROL		
	1.00	2.00	Total
DIABETE 1.00	475	656	1131
2.00	807	3229	4036
Total	1282	3885	5167

DIABETES * CONTROL Crosstabulation

		CON	TROL	
		1.00	2.00	Total
DIABETE 1.00	Count	475	656	1131
	% within DIABE	42.0%	58.0%	100.0%
	% within CONTI	37.1%	16.9%	21.9%
	% of Total	9.2%	12.7%	21.9%
2.00	Count	807	3229	4036
	% within DIABE	20.0%	80.0%	100.0%
	% within CONT	62.9%	83.1%	78.1%
	% of Total	15.6%	62.5%	78.1%
Total	Count	1282	3885	5167
	% within DIABE	24.8%	75.2%	100.0%
	% within CONTI	100.0%	100.0%	100.0%
	% of Total	24.8%	75.2%	100.0%

Hypothesis test:

H₀: There is no association between diabetes and heart disease. (or) Diabetes and heart disease are independent.

VS

H_A: There is an association between diabetes and heart disease. (or) Diabetes and heart disease are dependent.

--- Assume a significance level of 0.05

SPSS Output

Chi-Square Tests

		16	Asymp. Sig. (2-sided)	xact Sig.	xact Sig.
	Value	df	(2-sided)	<u>(2-sided)</u>	<u>(1-sided)</u>
Pearson Chi-Squ		1	.000		
Continuity Corre		1	.000		
Likelihood Ratio	212.149	1	.000		
Fisher's Exact T				.000	.000
Linear-by-Linear Association	229.224	1	.000		
N of Valid Cases	5167				

a.Computed only for a 2x2 table

b.0 cells (.0%) have expected count less than 5. The minimum e 280.62.

- ---The computer gives us a Chi-Square Statistic of 229.268
- ---The computer gives us a p-value of .000 (<0.0001)
- --- Because our p-value is less than alpha, we would reject the null hypothesis.
- --- There is sufficient evidence to conclude that there is an association between diabetes and heart disease.

Find out whether the gender is equally distributed among each age group

		Age		
Gender	<30	30-45	>45	Total
Male	60 (60)	20 (30)	40 (30)	120
Female	40 (40)	30 (20)	10 (20)	80
Total	100	50	50	200

Test for Homogeneity (Similarity)

To test similarity between frequency distribution or group. It is used in assessing the similarity between non-responders and responders in any survey

Age (yrs)	Responders	Non-responders	Total
<20	76 (82)	20 (14)	96
20 - 29	288 (289)	50 (49)	338
30-39	312 (310)	51 (53)	363
40-49	187 (185)	30 (32)	217
>50	77 (73)	9 (13)	86
Total	940	160	1100

Fisher's exact test:

Study variable: Qualitative(Categorical)

Outcome variable: Qualitative(Categorical)

Comparison: two proportions

Sample size: < 30

Example

The following data relate to suicidal feelings in samples of psychotic and neurotic patients:

	Psychotics	Neurotics	Total
Suicidal feelings	2	6	8
No suicidal feelings	18	14	32
Total	20	20	40

Example

The following data compare malocclusion of teeth with method of feeding infants.

	Normal teeth	Malocclusion
Breast fed	4	16
Bottle fed	1	21

Fisher's Exact Test:

The method of Yates's correction was useful when manual calculations were done. Now different types of statistical packages are available. Therefore, it is better to use Fisher's exact test rather than Yates's correction as it gives exact result.

Fisher's Exact Test = $\frac{R_1!R_2!C_1!C_2!}{n!a!b!c!d!}$

What to do when we have a paired samples and both the exposure and outcome variables are qualitative variables (Binary).

Macnemar's test: (for paired samples)

Study variable: Qualitative (categorical)

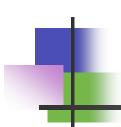

Outcome variable: Qualitative(categorical)

Comparison: two proportions

Sample size: Any

Problem

- A researcher has done a matched casecontrol study of endometrial cancer (cases) and exposure to conjugated estrogens (exposed).
- In the study cases were individually matched 1:1 to a non-cancer hospitalbased control, based on age, race, date of admission, and hospital.

McNemar's test

Situation:

- → Two paired binary variables that form a particular type of 2 x 2 table
- e.g. matched case-control study or cross-over trial

Data

	Cases	Controls	Total
Exposed	55	19	74
Not exposed	128	164	292
Total	183	183	366

- can't use a chi-squared test observations
- are not independent they're paired.
- we must present the 2 x 2 table differently
- each cell should contain a count of the number of pairs with certain criteria, with the columns and rows respectively referring to each of the subjects in the matched pair
- the information in the standard 2 x 2 table used for unmatched studies is insufficient because it doesn't say who is in which pair
 - ignoring the matching

Data

	Co		
Cases	Exposed	Not exposed	Total
Exposed	12	43	55
Not exposed	7	121	128
Total	19	164	183

We construct a matched 2 x 2 table:

	Co		
Cases	Exposed	Not exposed	Total
Exposed	е	f	ен
Not exposed	g	h	gur
Total	e l g	f + h	r

Formula

The odds ratio is: f/g

The odds ratio is:
$$f/g$$

The test is: $X^2 = \frac{(|f-g|-1)^2}{f+g}$

Compare this to the χ^2 distribution on 1 df

$$X^{2} = \frac{(|43-7|-1)^{2}}{43+7} = \frac{1225}{50} = 245$$

P <0.001, Odds Ratio =
$$43/7 = 6.1$$

p₁ - p₂ = $(55/183) - (19/183) = 0.197$ (20%)
s.e.(p₁ - p₂) = 0.036

95% CI: 0.12 to 0.27 (or 12% to 27%)

Degrees of Freedom df = (r-1) (c-1)= (2-1) (2-1) = 1

- Critical Value (Table A.6) = 3.84
- $X^2 = 25.92$
- Calculated value(25.92) is greater than critical (table) value (3.84) at 0.05 level with 1 d.f.f
- Hence we reject our Ho and conclude that there is highly statistically significant association between Endometrial cancer and Estrogens.

Two-tailed critical ratios of χ²

Degrees of freedom df	. 10	.05	.02	.01
1	2.706	3.841	5.412	6,635
2	4.605	5.991	7.824	9,210
3	6.251	7.815	9.837	11,341
4	7.779	9.488	11.668	13,277
5	9.236	11.070	13.388	15,086

In Conclusion!

When both the study variables and outcome variables are categorical (Qualitative):

Apply

- (i) Z-test (for one sample and two samples)
- (i) Chi square test(for two and more samples)
- (ii) Fisher's exact test (only two samples when sample size is small)
- (iii) Mac nemar's test (for paired samples)
