

Lecture Title:

RADIOLOGY OF SPINE DISEASES..

(RAD 366, Radiology)

Lecturer name: Dr. fahad albadr

Lecture Date: Jan 2019

Imaging Methods to Evaluate Spine

1. Plain X-Ray Films - bones
2. Myelogram – injection of contrast medium in CSF followed by x-ray images. Rarely performed now-a-days
3. Computed Tomography (CT Scan)
4. Magnetic Resonance Imaging (MRI)
5. Spinal angiography – to evaluate arteries and veins
6. Ultrasound – more in children
7. Radionuclide Bone Scan – intravenous injection of radioactive material bound to phosphonates which deposit in bones, followed by images by gamma camera.
8. DEXA – radionuclide scan for bone density (osteoporosis)

X-RAYS (RADIOGRAPHS)

Often the first diagnostic imaging test, quick and cheap

Small dose of radiation to visualize the bony parts of the spine

Can detect

- Spinal alignment and curvature
- Spinal instability – with flexion and extension views
- Congenital (birth) defects of spinal column
- Fractures caused by trauma
- Moderate osteoporosis (loss of calcium from the bone)
- Infections
- Tumors

May be taken in different positions (flexion and extension) to assess for instability

COMPUTERIZED TOMOGRAPHY (CT SCAN)

Uses radiation

Obtain 2-D images → can be processed to 3-D images

Patients lies on a table that moves through a scanner

Much detailed information regarding bony structures

Limited information about spinal cord & soft tissues

Entire spine can be imaged within a few minutes

COMPUTERIZED TOMOGRAPHY (CT SCAN)

Better in visualizing

- Degenerative or aging changes, Herniated discs
- Spinal alignment
- **Fractures and fracture patterns**
- Congenital / childhood anomalies
- Areas of narrowing in spinal canal through which spinal cord and spinal nerve roots pass

MYELOGRAM

A contrast material is injected into CSF to better identify areas where spinal cord or spinal nerves may be compressed

Magnetic Resonance Imaging (MRI)

The gold standard of imaging for spinal disorders

Does not use ionizing radiation

Can identify abnormalities of bone, discs, muscles, ligaments and spinal cord

Intravenous contrast is sometimes administered to better visualize certain structures or abnormalities

Patient lies still in a tunnel like structure for about 25 minutes

MRI SCANNER (closed type)

MRI SCANNER (open type)

MR images are multi-planar

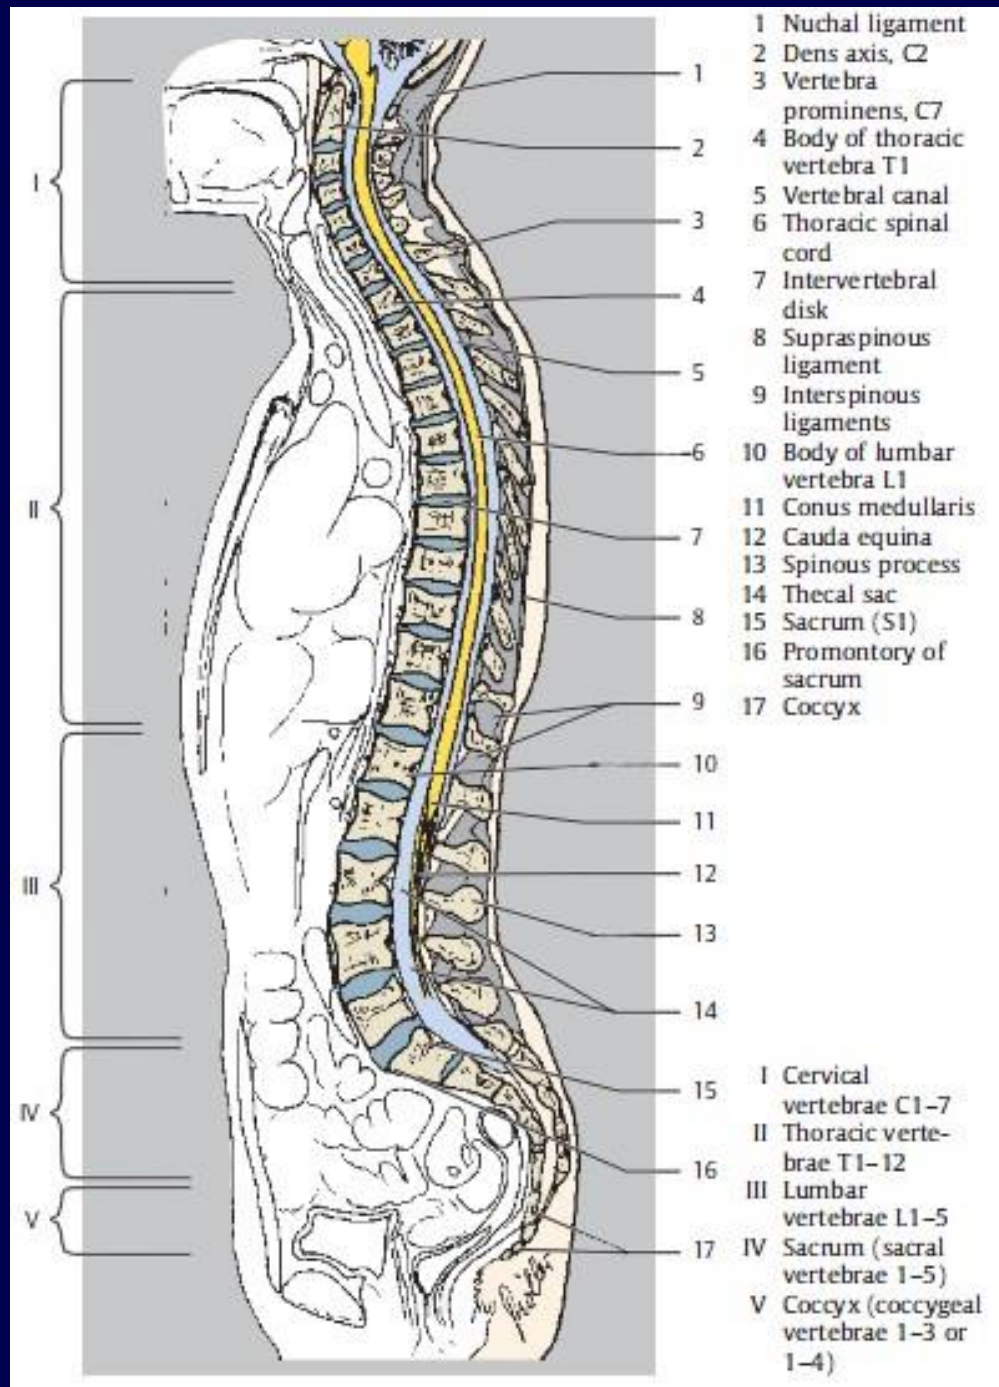

MR images are very high resolution

MR images are very high resolution

Congenital Anomalies

CONGENITAL ANOMALIES

MRI is the best to assess the contents of the cavity, extent of abnormalities, and spinal cord.

CT shows bony structures the best and is often used before surgery

Meningocele

Low lying cord tethered to large lipoma

Split low lying cord (diastematomyelia)

Multiple fusion abnormalities of vertebrae on plain film

TRAUMA

Plain film assessment of trauma – the first imaging method

Alignment should be normal – check by drawing lines

Soft tissue anterior to spine is
very important

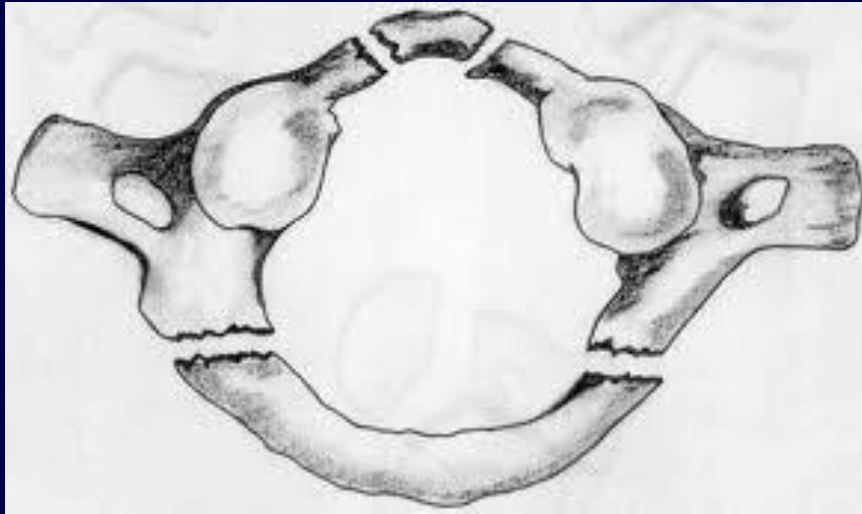

Jefferson Fracture

Lateral displacement of C1 in plain film (A)

Coronal reconstruction from a CT confirms the findings from the odontoid view

Axial CT clearly shows the location of the fractures of C1

Jefferson fracture

Posterior arch fracture

Hangman's Fracture

Hangman's Fracture

Fractures through the pars interarticularis of C2 resulting from hyperextension and distraction

Hyperextension (e.g. hanging, chin hits dashboard in road accident)

Radiographic features: (best seen on lateral view)

1. Prevertebral soft tissue swelling
2. Avulsion of anterior inferior corner of C2 associated with rupture of anterior longitudinal ligament.
3. Anterior dislocation of C2 vertebral body
4. Bilateral C2 pars interarticularis fractures

Burst fractures are a type of compression fracture related to high-energy axial loading spinal trauma that results in disruption of the posterior vertebral body cortex with retropulsion into the spinal canal.

INFECTIONS

Discitis and Osteomyelitis

Usually the result of blood-borne agents

Most common pathogen is staphylococcus, Streptococcus less common
Gram-negative rods in IV drug abusers or immunocompromised patients

E. Coli

Proteus

Non-pyogenic

Tuberculosis

Brucellosis

May occur after invasive procedure like Surgery, Discography, Myelography

In children, infection begins in vascularized disc

In adults, in anterior inferior corner of vertebral body with spread across disk to adjacent vertebral endplate

Discitis and Osteomyelitis

IMAGING FINDINGS

PLAIN FILMS

- Narrowing and destruction of an intervertebral disk
- Indistinct adjacent endplates with destruction
- Often associated with bony sclerosis of the two contiguous vertebral bodies
- Paravertebral soft tissue mass
- Endplate sclerosis (during healing phase beginning anywhere from 8 weeks to 8 months after onset)
- Bone fusion after 6 months to 2 years

MRI

- Bone marrow edema in infected vertebrae, discs and paraspinal soft tissues
 - Dark on T1 and bright on T2 images
- Enhancement of inflamed tissues after contrast
- Fluid collections (abscesses) are common

Spondylo-discitis

Narrow and destruction of L3-L4 disc space with irregular erosions of opposing endplates

Spondylo-discitis

Sagittal T1WI shows decreased signal of vertebral bodies and disc with end plate destruction.

Sagittal T2WI shows increased signal in corresponding areas with anterior subligamentous and intraspinal epidural abscess.

Sagittal contrast-enhanced T1-fat sat shows intense enhancement the involved area

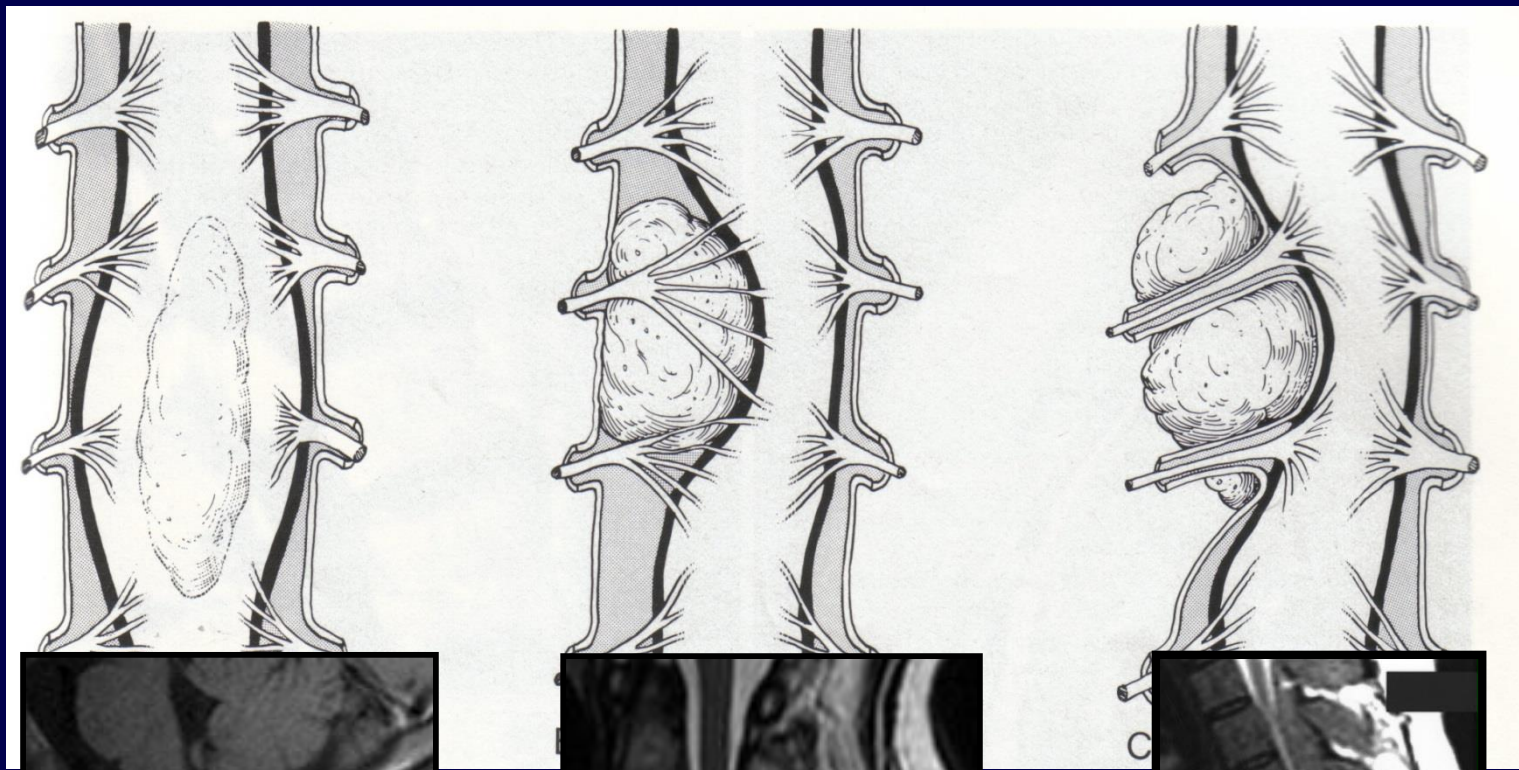

Axial T2WI and axial contrast-enhanced T1 fat sat show the para spinal large abscesses

TUMORS

Ependymoma

Astrocytoma

INFLAMMATORY

Multiple Sclerosis

MS is an immune-mediated inflammatory demyelinating disease of the brain and the spinal cord.

MS is the most common demyelinating disease and there is overlap between these diseases:

- NMO was first thought to be a form of MS, but is now considered to be a distinct form.
- ADEM can relapse and progress to MS.
- The partial form of transverse myelitis.

Multiple Sclerosis

SPINAL CORD LESIONS

- Mostly in cervical cord (60%) and conus
- Less commonly in thoracic region
- More than 1 lesion in 55%
- <2 segments (2-60mm) in craniocaudal length
- Eccentric
- No or very little mass effect or cord swelling
- Lesions only in spinal cord in 5-24%
- May result in cord atrophy → Disability

Multiple Sclerosis

On transverse images MS lesions typically have a round or triangular shape and are located posteriorly or laterally.

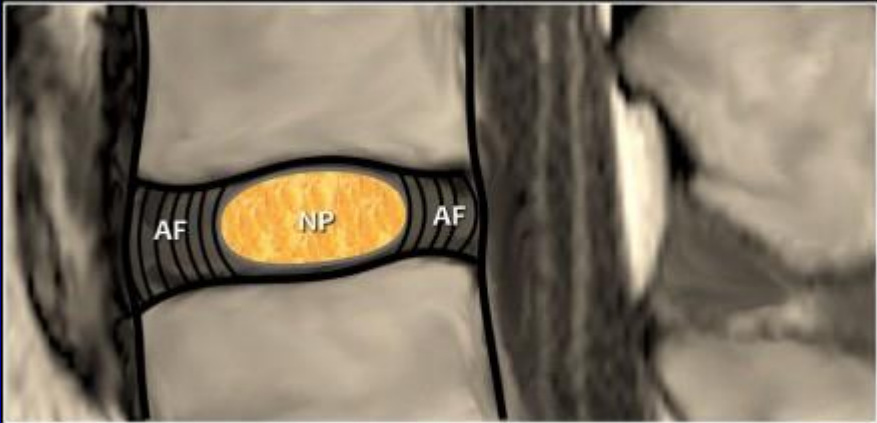

DISC DISEASE

DISC DISEASE

DISC DISEASE

Disc herniation with sequestered disc fragment
