Substance Use Disorders

By: Dr. Majid Al-Desouki
Consultant and Clinical Assistant Professor

- •Go to:
- www.quizizz.com

Introduction

- Many implications for brain research & clinical psychiatry.
- Affect mental state and behavior.
- Sx similar to the psychiatric disorders.

What is addiction?

 In Aug 2011, The American Society of Addiction Medicine (ASAM) has officially recognized Addiction as mostly:

- a) a social problem
- Addiction is not a choice, but choice still plays an important role in getting help.
- e) a behavioral or rde causes such semotional or psychiatric problems.

Terminology

Abuse: self-administration of any substance in a culturally disapproved manner that causes adverse consequences.

Intoxication: the transient effect (physical and psychological) due to recent substance ingestion, which disappears when the substance is eliminated.

Withdrawal: a group of symptoms and signs occurring when the drug is withdrawn or reduced in amount.

Terminology (cont.)

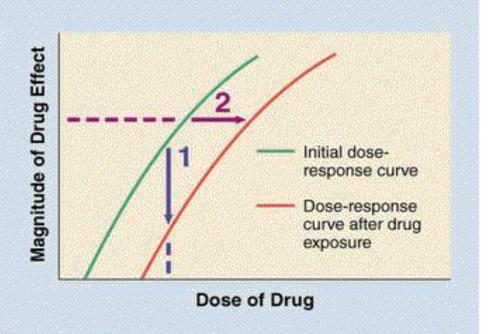

Dependence: the physiological state of neuroadaptation produced by repeated administration of a drug, necessitating continued administration to prevent appearance of withdrawal state.

Addiction: a nonscientific term that implies dependence and associated deterioration of physical mental health as well as high tendency to relapse after discontinuation.

▶ Drug Tolerance

Drug tolerance is a shift in the dose-response curve to the right. Therefore,

- 1 In tolerant subjects, the same dose has less effect
- 2 In tolerant subjects, a greater dose is required to produce the same effect

Complications

Psychological

Social

Medical

Basic classification

CNS Suppressants

Alcohol - Sedatives - Inhalants - Opioids.

CNS Stimulants: Amphetamine – Cocaine

Cannabis

Assessement

- Collateral history.
- Urine screening tests.
- blood screening tests (alcohol, barbiturates).
- Pattern of Abuse:
- What? (type, dose, route, effect: nature and duration).
- How? (frequency, duration, how long, source, and situation)
- Why? (? psychosocial problems).
- Dependence?

- Complications :
- Psychosocial.....
- Physical.....

Alcohol and Related Mental Disorders

Alcohol Kills More Than AIDS, TB or Violence-WHO report (Feb 2011)

- Alcohol causes nearly 4% of deaths worldwide, more than AIDS, tuberculosis or violence.
- Alcohol is the world's leading risk factor for death among males aged 15-59
- Alcohol is a causal factor in 60 types of diseases and injuries.

Risk factors of Alcohol abuse

- Vulnerable personality: impulsive, gregarious, less conforming, isolated or avoidant persons.
- Vulnerable occupation: senior businessmen, journalists, doctors.
- Psychosocial stresses: social isolation, financial, occupational or academic difficulties, and marital conflicts.
- Emotional problems: anxiety, chronic insomnia depression.

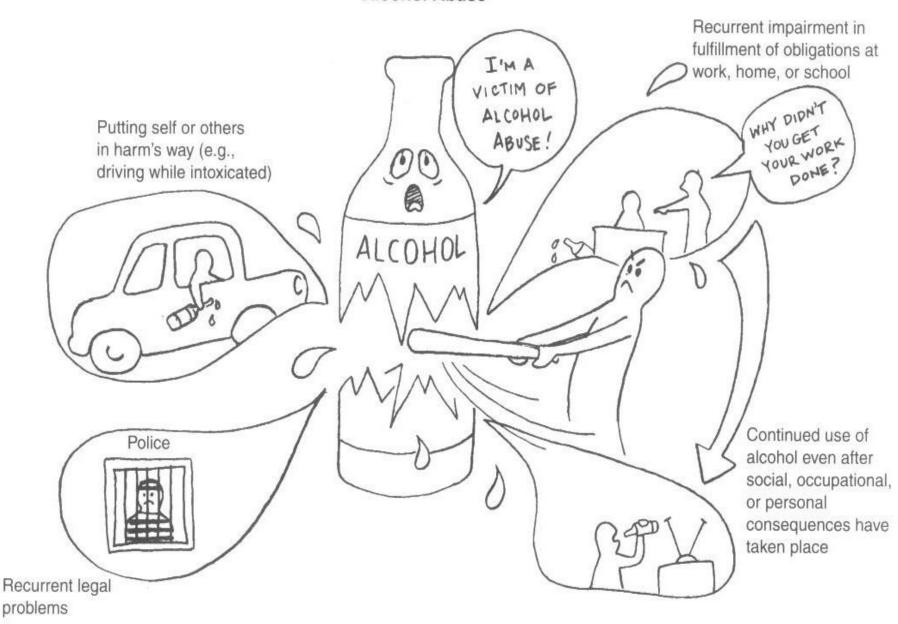

Alcohol abuse

Excessive consumption: harmful use.
 Problem drinking: drinking that has caused disability, but not dependence.

Alcohol dependence: This usually denotes alcoholism.

Alcohol-related disability: physical, mental and social.

Alcohol Abuse

How much is too much?

Clinical presentation

• Alcohol intoxication:

- sense of well-being, emotional lability, irritability and incoordination
 to ataxia and slurred speech
- Heavy intoxication (bl > 300 mg/ml) → alcoholic coma & death
- Acute intoxication may mimic:
 - panic attacks
 - Depression
 - acute psychosis with delusions +/- hallucinations

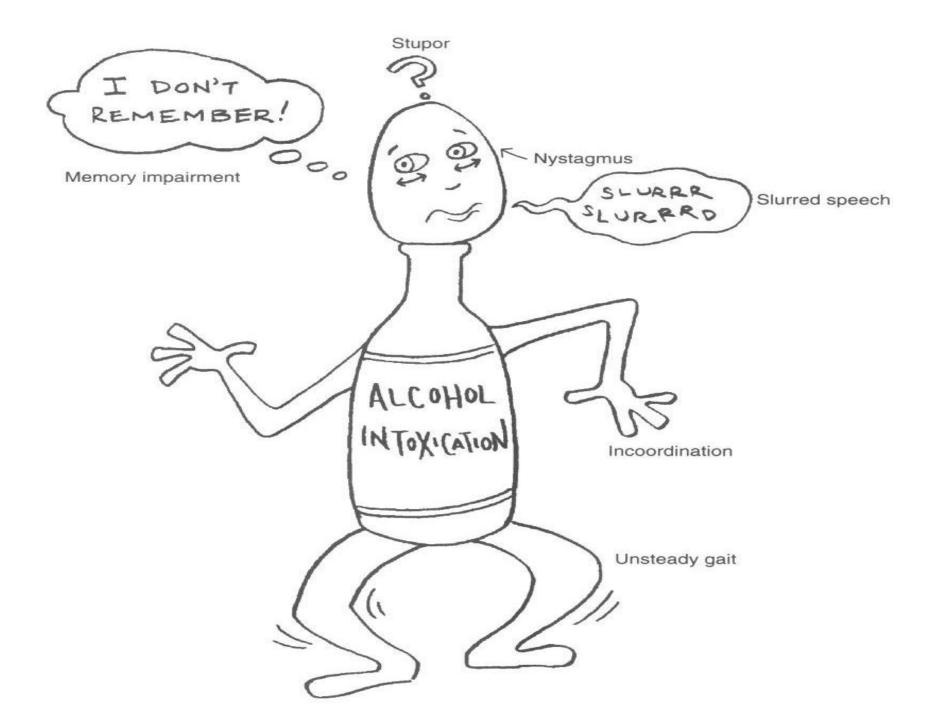

Alcohol intoxication Ethanol plasma concentrations Vs. CNS effects

Ethanol plasma concentration (mg/dL)	Impairment
	Feeling of relaxation, euphoria
20-30	Slowed thinking
30-80	Motor incoordination
80-200	Cognition, judgement, labilty
200-300	Slurring, ataxia, nystagmus, blackouts
>300	Vital signs, coma, possible death due to the respiratory failure

Clinical presentation (cont)

• Alcohol withdrawal:

- Sx may begin after 6 hours of cessation peak by 48 hours
- Sx subside over the course of 5-7 days
- epileptic generalized tonic clonic seizures may develop within 12-24 hours after cessation of alcohol intake
- Delirium tremens may develop after about 48 hours

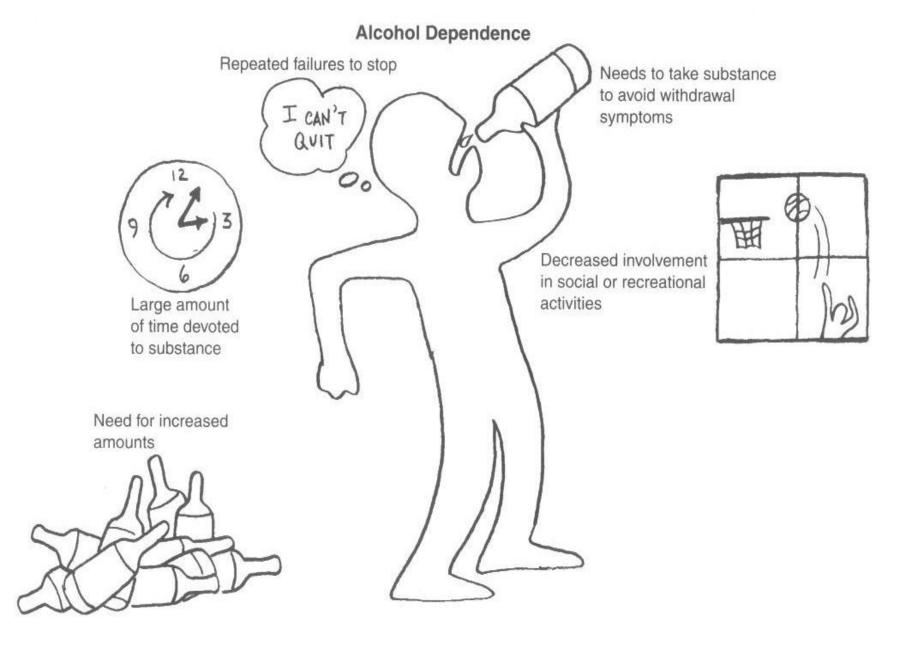

Alcohol dependence

- 15-20 years before evident
- dependence is most common in those aged 40 – 55 years.
- Alcoholics who continue drinking have a shortened lifespan of <u>15 years</u> why?

Complications of chronic alcohol abuse

Medical	Psychiatric	Social
Neurological	Amnestic disorder	Social isolation
Cerebral degeneration	Delirium	
Seizures	Dementia	Job loss
Peripheral neuropathy	Psychosis	
Optic nerve atrophy	Depression	Marital conflicts
Alimentary Tumors	Reduced sexual desire	
(esophagus, liver)	Insomnia	Family problems
Gastritis, peptic ulcer	Personality	
Pancreatitis	deterioration	Legal troubles
Hepatitis, liver cirrhosis	Increased risk of	
Cardiomyopathy	suicide	Social stigma
Anemia	Morbid jealousy	
Gynaecomastia		

Screening – CAGE questionnaire

- Have you ever:
- 1. Wanted to cut down on your drinking?
- 2. Felt annoyed by criticism of your drinking
- 3. Felt *guilty* about drinking?
- 4. Take a drink as an "eye-opener" to prevent the shakes?

Laboratory Tests

- Identify acute and/or heavy drinking (≥ 5 drinks/day):
 - Blood Alcohol Levels (BAL).
 - ☐ Gamma-glutamyltransferase (GGTP > 35 IU/L)
 - \square Erythrocyte mean corpuscular volume (MCV >91.5 μ^3)
 - ☐ High AST/ALT

Treatment

Treating Alcohol Intoxicated Patient:

Conscious: supportive, antipsychotic if agitated. Unconscious: ABC

Treating Alcohol Withdrawal:

Supportive, thiamine & long acting BDZ ± anticonvulsants for seizure.

- Maintaining Abstinence:
 - Disulfiram blockade of aldehydedehydrogenase → cummulation of acetaldehyde - nausea, flushing, tachycardia, hyperventilation, panic...
 - Naloxone reduces alcohol-induced reward.
 - Acamprosate anti-craving effects.
- Psychological: Individual, group Rx, relapse prevention.

Delerium Tremens (DTs)

Severe form of alcohol withdrawal after 2-3 days:

- gradual onset of delirium and gross tremors

Other features:

- autonomic disturbance
- dehydration and electrolyte disturbance
- insomnia
- Peaks on 3rd or 4th day
- Lasts 3-5 days
- Worse at night and followed by a period of prolonged deep sleep after which the pt has amnesia

Complications include:

- 1. Violent behavior
- 2. Seizures (chest infection & aspiration)
- 3. Coma
- 4. Death (mortality rate: 5-15%)

Causes:

- 1. Volume depletion
- 2. Cardiac arrhythmias
- 3. Electrolyte imbalance
- 4. Infections

Treatment

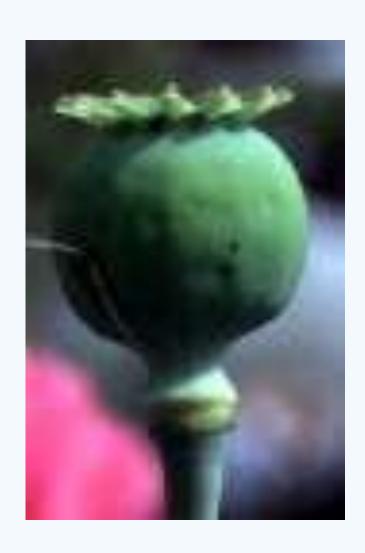

- 1. DT is a serious MEDICAL emergency → detection and treatment ICU or medical ward
- 2. Avoid antipsychotics
- 3. Guard against seizures
- 4. Rehydration
- 5. Thiamine (B1)
- 6. Adjust surroundings

Sedatives, Hypnotics, and Anxiolytics

- Similar clinical manifestations and withdrawal to alcohol.
- Risk of cross-tolerance and cross-dependence?
- Withdrawal depends on substance
- BDZ have a large margin of safety & less addiction potentials.
- Flumazenil is a BDZ receptor antagonists used in BDZ overdose.

OPIOIDS

- 1. Opium
- 2. Heroin
- 3. Morphine
- 4. Codeine
- 5. Pethidine
- 6. Methadone
- naturally occurring (e.g. opium, codeine), synthetic or semisynthetic
- medical use pethidine or substance of abuse heroin
- The medical use powerful analgesic effect
- Abused for euphorsant effect

Opiod intoxication

Presentation	Treatment
Euphoria	ICU:
Relaxation	Monitoring
Anelgesia	Naloxone
Disturbed	Open airway – oxygen
consciousness	IV fluids
Small pupil (initially)	
Bradycardia	
Reduced appetite	
Constipation	
Respiratory depression	

Potency?!

Opioid withdrawal

Presentation	Treatment
 Lacrimation, rhinorrhea & yawning Dysphoric mood Insomnia Muscle and joint aches Cold and hot flushes Nausea, vomiting and diarrhea Fever, sweating, piloerection 	Short-term: Painkillers, sedatives, observation Clonidine Long-term Harm reduction strategies Methadone Buprenorphine/Naloxone

Intense craving begins 6 hours after the last dose and peaks after 36-48 hours

Untreated withdrawal result in no serious medical sequence - but they cause great distress

Tolerance can develop very rapidly (esp. in IV use) leading to increasing dosage - then it diminishes very rapidly

Complications of injecting

- Bacterial, local and systemic
- Blood-borne viruses
- Vascular damage

- In this case:
 - Track marks
 - Early cellulitis
 - Multiple injections over a short period suggests cocaine use

 Adeeb is a 16 year old boy who lives with his divorced mother. He presented with slurred speech, facial rashes, incoordination and nausea.

Inhalants

- Volatile organic substances –acetone, benzene, etc.
- Brain depressants
- Adolescents experimentations
- Intoxication similar to other brain suppressants
- Complications:
 - Physical: multiple organ damages

 Rakan is a 20-year old male brought to the ER by police who arrested him because of reckless driving (drifting with high speed) and violent behavior. He looked over-suspicious, agitated, and over-talkative.

Psychostimulants

Commonly used Stimulants

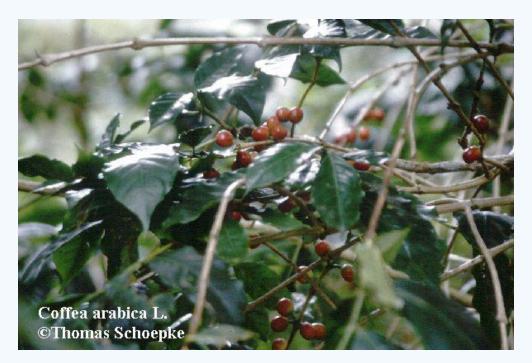

- Nicotine
- Caffeine
- Cocaine Freebase/crack
- Amphetamine/Methamphetamine
- Methylenedioxymethamphetamine (MDMA)
- Appetite suppressants
 - (e.g. phentermine and diethylpropion)

Psychological FX of non dependent use

- Recurrent intoxication
- Some users may self-medicate with antidepressants and/or benzodiazepines
- After-effects: termed 'crash' or 'come down'
 - Dysphoria
 - Depressed mood
 - Anxiety
 - Reduced appetite
 - Restlessness

Clinical effects of stimulants

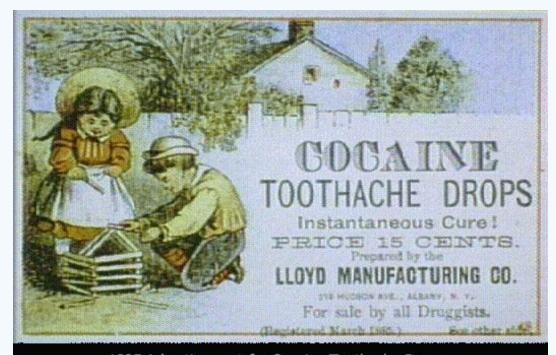

Psychological	Physical
Enhanced cognitive function	Reduced sense of fatigue
Elevated mood	Reduced appetite (anorexia)
Over activity	Dilated pupils
Increased confidence, self- esteem and sociability	Tremors
Overtalkativeness	In high doses/prolonged use:
Insomnia	Nausea, vomiting, hyperthermia,
In high doses/prolonged use:	cardiac arrhythmias, severe
Restlessness, irritability	hypertension, CVA, seizures
Paranoid psychosis,	Dizziness, respiratory distress,
hallucinations (visual)	
Aggressiveness, hostility	

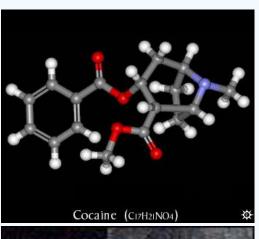

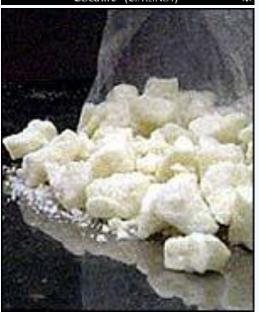

1885 Advertisement for Cocaine Toothache Drops

Cocaine

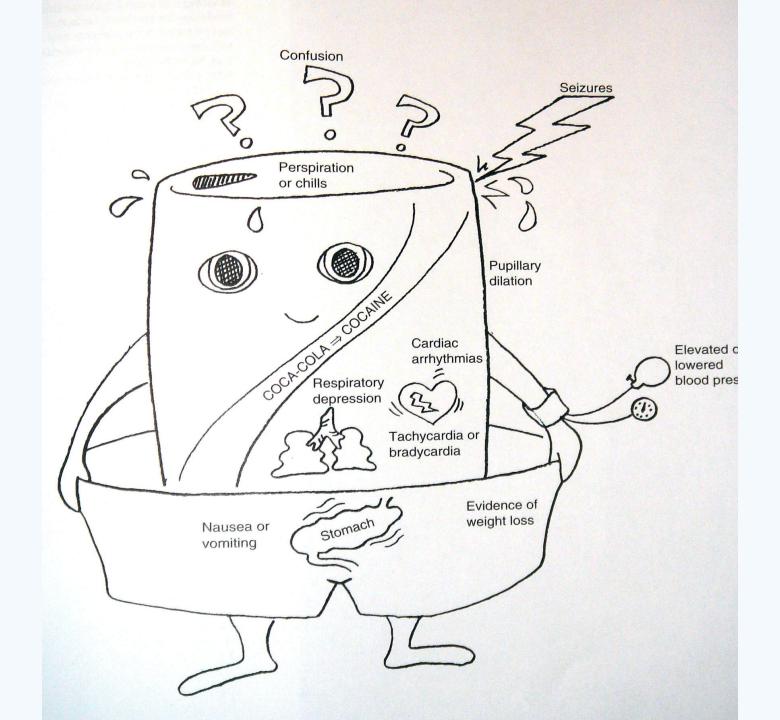

- Forms of cocaine:
 - Free base
 - Crack

- Routes of use:
 - Intranasal
 - Intravenous/SC

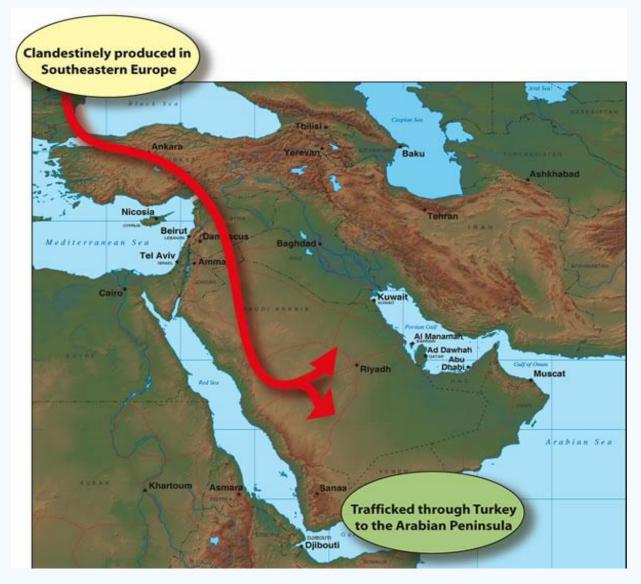

Crack cocaine

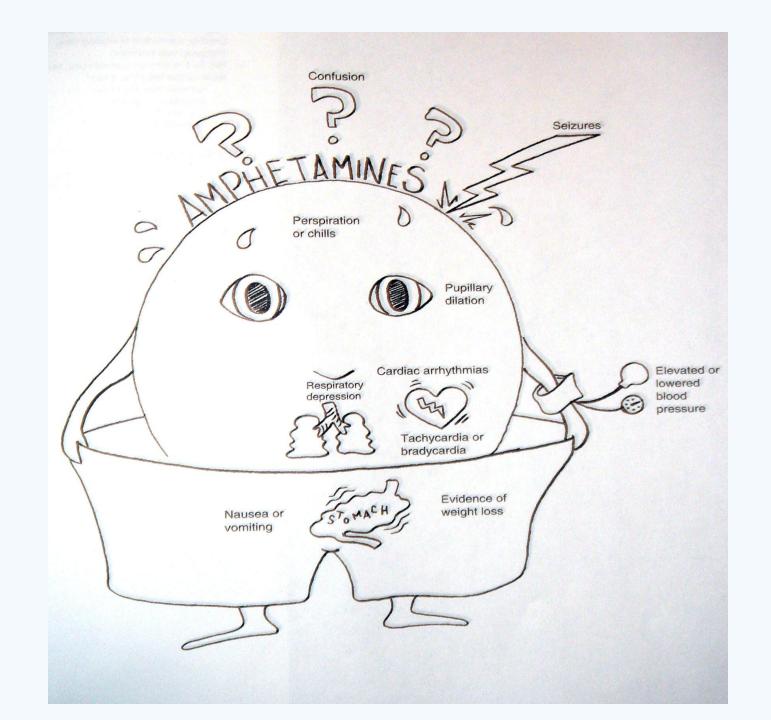

Captagon (Fenethylline)

Treatment

- Symptomatic use of antipsychotic
- Antidepressant sometimes useful
- Psychotherapy (individual, family & group)

Hallucinogens

- These are group of substances that induce hallucination and produce loss of contact with reality
- Natural and synthetic substances that are also called psychedelics or psychotomimetics
- Natural e.g. psilocybin (magic mushroom) or synthetic like lysergic acid diethylamide (LSD)
- No medical use and high abuse potential

Clinical effects

Psychological	Physical
Marked perceptual distortion (changing shapes and colors) Hallucination (visual and tactile) False sense of achievement and strength Euphoria, anxiety, panic Paranoid ideation Homicide and suicide tendencies Flashbacks Delirium	Tachycardia Hypertension Cerebellar signs Wide pupils Hyperemic conjunctiva Blurred vision Hyperthermia

Effects of LSD

Effects of drug come on in about 30 min

- first signs are autonomic activation
- followed by overt behavioral signs loosening of emotional inhibitions
 - giddiness, laughter for no reason
 - mood euphoric and expansive, but labile mood swings notable
- abnormal color sensations, luminescence
- colors reported as more brilliant

Effects of LSD

- space and time disorders
- added depth with loss of perspective up/down altered
- close in space influenced more than distant
- general slowing of time reported

Tolerance/Dependence

- Not significant producers of tolerance or dependence
- No withdrawal either
- Problems related to the things people do while under the influence
 - Accidents
 - Suicide
 - Aggression/violence
 - Toxic reactions

New Psychoactive Substances (NPS)

Variable quantity and potency (up to 10,000 x morphine)

Synthetic Cathinones

Synthetic Cannabis

Synthetic Benzodiazepines

 Bandar is a 32-year old male brought to outpatient clinic by his wife because of recurrent periods of being over-suspicious, euphoric, and talkative. He admitted abusing cannabis in the weekends.

CANNABIS

What is Cannabis (marijuana)?

Cannabis sativa.

- psychoactive cannabinoids, (delta9-THC) is most abundant.
- From flowering tops of the plants or from the dried, black- brown, resinous exudates from the leaves (hashish).
- Common names: marijuana, grass, pot, weed, tea, and Mary Jane.

What are the acute effects?

- When smoked, euphoric effects appear within minutes, peak in about 30 minutes, and last 2 to 4 hours.
- If ingested, short term effects begin more slowly, usually 0.5 to 1h.
- After few min. heart begins beating, the bronchial passages relax and became enlarged, and the blood vessels in the eyes look red.
- THC activates the reward system releasing dopamine.

What are the acute effects?

- A pleasant sensation, color and sounds may seem more intense, and time appears to pass very slowly, mouth feels dry and he or she become very hungry and thirsty.
- THC disrupts coordination and balance.
- Anxiety +/- panic attacks
- High doses may cause acute toxic psychosis.
- Amotivational syndrome

Effect on physical health?

- Increases difficulty in trying to quit smoking tobacco.
- Red eyes, tachycardia. At high doses: orthostatic hypotension, increased appetite & dry mouth.
- Heavy users are at risk for chronic respiratory disease
- Also associated with: cerebral atrophy, seizure susceptibility, chromosomal damage, birth defects, impaired immune reactivity, alterations in testosterone conc. & dysregulation of menstrual cycles.
- Same carcinogenic hydrocarbons in conventional tobacco.

Treatment

- Same principles as Rx of other substances of abuseabstinence and support
- Education is cornerstone for both abstinence & support.
- Support through individual, family, and group psychotherapies.
- Antipsychotic medication
- Anti-anxiety/antidepressant drug may be useful

- A 41-year-old businessman came to the emergency department complaining of insomnia for 3 days after he ran short of his sleeping pills. He was asking for a specific drug manufactured by ROCHE Company. He knows that each tablet is 2 mg. He said he uses 5 tablets each night to sleep. The most likely problem of this patient is:
 - Heroin abuse.
 - Benzodiazepines abuse.
 - Methadone abuse.
 - Abuse of painkillers.

- A 33-year-old single man was caught by police officers and put in prison because he was driving his car recklessly with high speed at 3am in the highway. Next day he started to show excessive lacrimation, runny nose, repeated vomiting, and abdominal cramps. However, his consciousness was intact. The most likely problem of this patient is:
 - Cannabis abuse.
 - Methadone intoxication.
 - Abuse of naloxone.
 - Opioid withdrawal.

- A 32-year-old man became increasingly irritable, insomniac, hypervigilant for the past 4 weeks with unpredictable mood and accusing his wife with extramarital sexual relationships. The most likely diagnosis is:
 - Heroin abuse.
 - Generalized anxiety disorder.
 - Amphetamine abuse.
 - Paranoid Schizophrenia.

 A 43-year-old man has episodic behavioral disturbances including; euphoria, talkativeness, and disinihibition.

His eyes look red most of the time. The most likely diagnosis is:

- Alcohol abuse.
- Cannabis abuse.
- Amphetamine abuse.
- Cocaine abuse.

- A 16-year-old boy presented with slurred speech, incoordination and nausea. Physical examination revealed facial rashes around his mouth and nose. When asked about substance abuse his reply was affirmative. The most likely substance is:
 - Cannabis.
 - Alcohol.
 - Volatile substance.
 - Morphine.
